SOME STREAM WATERS OF THE WESTERN UNITED STATES.

By Herman Stabler.
[Analyses by chemists of the United States Reclamation Service.]

INTRODUCTION.

HISTORY OF THE INVESTIGATIONS.

A systematic study of the waters likely to be utilized on the Reclamation Service projects was made in order to determine the influence of the salinity of the waters on the growth of vegetation and the effect of suspended matter in silting canals and reservoirs.

The work was begun early in 1905, under the direction of Thomas H. Means, engineer, and was continued during 1906 and until May, 1907, under the direction of W. H. Heileman, engineer. The analyses were made in a laboratory established at quarters provided by the University of California at Berkeley, Cal., by C. H. Stone, P. L. McCreary, F. M. Eaton, O. J. Hawley, W. C. Riddell, F. T. Berry, H. A. Burns, J. H. Hampson, J. A. Pearce, and M. Vaygouny, the greater part of the work being that of the first five named. C. H. Stone was chemist in charge at the beginning of the investigations and is chiefly responsible for the plan of the analytical work and the methods of analysis.

The results of the investigations were prepared for publication under instructions from F. H. Newell, Director of the United States Reclamation Service, by Herman Stabler, assistant engineer, who assembled and checked the analyses, compiled the accompanying stream-flow data from records of the United States Geological Survey, and computed daily discharge of suspended matter and dissolved solids, under the supervision of D. W. Murphy, engineer in charge of Washington office engineering.

COLLECTION OF SAMPLES.

Samples were collected for an extended period at 55 stations, located for the most part at established gaging stations of the United States Geological Survey in order that stream-flow data concurrent with the analyses might be obtained.

The general plan of sample collection provided for the taking of 4 ounces of water each day at each of the regular stations. The point

of collection was selected with a view to obtaining a fair average sample of the water flowing in the stream, and occasionally samples were taken from different parts of the cross section in order to determine any possible local variation in quality of water. The general plan could not be followed absolutely, and the records show numerous gaps caused by noncollection of samples, loss of samples in transit, or by other reasons.

The results of the work are here presented in alphabetical order by stream names and, under the stream names, by station names. The following lists classify the stations by drainage basins and by States.

Sampling stations, by drainage basins.

Colorado River basin:
- Colorado River near Yuma, Ariz.
- Green River near Green River, Wyo.
- Jensen, Utah.
- Grand River basin:
  - Grand River near Kremmling, Colo.
  - Palisade, Colo.
  - Gunnison River near Whitewater, Colo.
- San Juan River basin:
  - Animas River near Durango, Colo.
- Little Colorado River near Holbrook, Ariz.
- Woodruff, Ariz.
- Gila River basin:
  - Gila River near San Carlos, Ariz.
  - San Francisco River near Alma, N. Mex.
  - Salt River basin—
    - Salt River near Roosevelt, Ariz.
    - Verde River near McDowell, Ariz.

Columbia River basin:
- Snake River basin:
  - Boise River near Boise, Idaho.
  - Malheur River near Vale, Oreg.
  - Payette River near Horseshoe Bend, Idaho.
- Palouse River near Hooper, Wash.
- Okanogan River basin:
  - Salmon Creek near Malott, Wash.

Great Basin:
- Carson River near Hazen, Nev.
- Truckee River near Derby, Nev.
- Owens River near Round Valley, Cal.
- Tinemaha, Cal.

Klamath River basin:
- Link River near Klamath Falls, Oreg.

Mississippi River basin:
- Missouri River basin:
  - Milk River near Havre, Mont.
  - Yellowstone River basin:
    - Yellowstone River near Billings, Mont.
    - Glendive, Mont.

Mississippi River basin—Continued.
Missouri River basin—Continued.
Yellowstone River basin—Continued.
Bighorn River basin:
Bighorn River near Fort Custer, Mont.
Shoshone River near Cody, Wyo.
Cheyenne River basin:
Belle Fourche River at county bridge near Belle Fourche, S. Dak.
diversion dam near Belle Fourche, S. Dak.
Redwater River near Belle Fourche, S. Dak.
Arkansas River basin:
Canadian River basin:
Sapello River near Los Alamos, N. Mex.
Red River basin:
Salt Fork of Red River—
Salt Fork of Red River near Mangum, Okla.
Turkey Creek near Olustee, Okla.
North Fork of Red River:
North Fork of Red River near Granite, Okla.
Headrick, Okla.
Elm Fork near Mangum, Okla.
Rio Grande basin:
Rio Grande near San Marcial, N. Mex.
El Paso, Tex.
Pecos River basin:
Pecos River near Santa Rosa, N. Mex.
near Dayton, N. Mex.
at Carlsbad, N. Mex.
Gallinas River near Las Vegas, N. Mex.
Hondo River near Roswell, N. Mex.
Sacramento River basin:
Sacramento River near Red Bluff, Cal.
at Sacramento, Cal.
Pit River near Bieber, Cal.
Stony Creek near Fruto, Cal.
Feather River basin:
Feather River near Oroville, Cal.
Yuba River near Smartsville, Cal.
American River near Fairoaks, Cal.
Puta Creek near Winters, Cal.
San Joaquin River basin:
Tuolumne River near La Grange, Cal.

Sampling stations and streams, by States.

Arizona:
Holbrook, Little Colorado River.
McDowell, Verde River.
Roosevelt, Salt River.
San Carlos, Gila River.
Woodruff, Little Colorado River.
Yuma, Colorado River.
California:
Bieber, Pit River.
Fairoaks, American River.
Fruto, Stony Creek.

California—Continued.
La Grange, Tuolumne River.
Oroville, Feather River.
Round Valley, Owens River.
Red Bluff, Sacramento River.
Sacramento, Sacramento River
Smartsville, Yuba River.
Tinemaha, Owens River.
Winters, Puta Creek.
Colorado:
Durango, Animas River.
Kremmling, Grand River.
Palisade, Grand River.
Whitewater, Gunnison River.
Idaho:
Boise, Boise River.
Horseshoe Bend, Payette River.
Montana:
Billings, Yellowstone River.
Fort Custer, Bighorn River.
Glendive, Yellowstone River.
Havre, Milk River.
Nevada:
Derby, Truckee River.
Hazen, Carson River.
New Mexico:
Alma, San Francisco River.
Carlsbad, Pecos River.
Dayton, Pecos River.
Las Vegas, Gallinas River.
Los Alamos, Sapello River.
Roswell, Hondo River.
San Marcial, Rio Grande.
Santa Rosa, Pecos River.
North Dakota:
Williston, Missouri River.
Oklahoma:
Granite, North Fork of Red River.
Headrick, North Fork of Red River.
Mangum, Elm Fork.
Mangum, Salt Fork of Red River.
Olustee, Turkey Creek.
Oregon:
Klamath Falls, Link River.
Vale, Malheur River.
South Dakota:
Belle Fourche, Belle Fourche River at county bridge.
Belle Fourche, Belle Fourche River at diversion dam.
Belle Fourche, Redwater River.
Texas:
El Paso, Rio Grande.
Utah:
Jensen, Green River.

Washington:
Hooper, Palouse River.
Malott, Salmon Creek.
Wyoming:
Cody, Shoshone River.
Fort Laramie, North Platte River.
Green River, Green River.

In addition to the analyses of samples taken at these regular stations, many analyses were made of samples collected from various miscellaneous sources. The results of these miscellaneous analyses are tabulated under appropriate headings on pages 141 to 149.

PLAN OF ANALYTICAL WORK.

Equal volumes of the individual samples were united to form composite samples representing the average quality of the water of each stream for a week. The weekly samples were analyzed quantitatively for total solids, dissolved solids, and the carbonate, bicarbonate, and chlorine radicles, and qualitatively for the sulphate radicle. Remainders of the weekly composites were combined in sets of four representing the collections for a month. The monthly composites thus obtained were analyzed quantitatively for dissolved solids and the calcium, magnesium, sodium and potassium, carbonate, bicarbonate, sulphate, chlorine, and nitrate radicles. The suspended matter from the monthly composites for some streams was accumulated and analyzed. Variations from the regular plan of analytical work are shown by the dates of samples in the tables.

METHODS OF ANALYSIS.

The analyses are reported in milligrams per liter, a unit which for little-mineralized water is practically synonymous with parts per million and which was selected because it can more accurately represent the high mineral content of such waters as are found in some of the western streams.

Of the weekly composites 50 cubic centimeters was taken and total solids were determined by evaporating to dryness on a steam bath, drying for one hour at 110° C., cooling in a desiccator, and weighing. Solids were estimated on both filtered and unfiltered samples, and the difference between the two determinations was tabulated as suspended matter. Of the monthly composites 200 cubic centimeters of filtered water was taken for the dissolved solids determination.

Great difficulty was experienced in securing clear filtrates for the determination of dissolved solids and the radicles because of the great quantity of very fine material carried in suspension by many of the streams. For the first few months a filter pump was used successfully and then the Shimer method[a] was adopted, the procedure being

[a] Jour. Am. Chem. Soc., Mar., 1905.

about as follows: A Swedish filter paper, beaten to a pulp in a paraffin vessel with hydrochloric and hydrofluoric acids and washed, was spread on a felt pad placed in the bottom of a long cylindrical glass tube tightly fitted to a suction flask. The sample to be filtered was placed in the cylindrical tube and suction applied. When sufficient filtrate had been obtained the filter was washed with distilled water to prepare it for the next sample.

Carbonate, bicarbonate, and chlorine radicles were in general determined as follows: Fifty cubic centimeters of the filtered sample was placed in a dish, phenolphthalein indicator added, and titration made with sodium acid sulphate solution to the end point; methyl orange indicator added and titration continued to a second end point; potassium chromate indicator added and titration with silver nitrate made to a third end point. The titrations with sodium acid sulphate furnished data for the calculation of carbonate and bicarbonate radicles and the titration with silver nitrate furnished data for the calculation of the chlorine radicle. In analyzing some of the more concentrated waters less than 50 cubic centimeters of water was used.

Calcium, magnesium, sodium and potassium, and sulphate radicles were determined gravimetrically by the methods of Fresenius. In a few analyses separation of sodium and potassium was made gravimetrically. The figure representing sodium and potassium together was obtained by calculating the weight of their combined chlorides to sodium. The result is in reality the amount of sodium plus three-fourths the potassium, and is so reported in the tables. Where sodium and potassium were separated these bases are reported in terms of per cent of $(Na + \frac{3}{4}K)$.

The nitrogen and other determinations of sanitary analyses were made in accordance with the standard methods of the American Public Health Association.

Special methods of analysis were used from time to time, and for the Colorado at Yuma the methods used by Forbes[a] in previous work on this stream were adopted. These methods differed from those used on other streams as follows: All evaporations were made in porcelain instead of silver or platinum, the liquid was measured in a pipette instead of a flask, the dissolved solids were determined on the clear supernatant liquid after standing several days instead of on a filtered portion of the sample, and 100 cubic centimeters was used for the solids determinations instead of 50 cubic centimeters.

ACCURACY OF WORK AND TABLES.

The partial analyses of weekly composites have been checked as far as possible and the qualitative determinations of sulphates and all apparently erroneous values have been omitted.

[a] Forbes, R. H., The river irrigating waters of Arizona: Bull. 44, Univ. Arizona Agr. Exper. Sta.

As the remainders of the weekly composites used for the monthly composites were not united in equal parts or in proportion to stream flow, the analytical results may not represent with great accuracy the mean quality of the water or the quality of the mean flow. The monthly analyses are therefore presented in terms of per cent of dissolved solids, for the percentage composition varies little with changes in stream flow. The per cents are not intended to indicate the percentage composition of the dissolved solids but are merely ratios, expressed as per cent, of the various radicles to the dissolved solids determinations. The actual quantities in milligrams per liter of the various radicles may be estimated by applying the tabulated per cents to the mean of the dissolved solids results of the weekly analyses for any period. In the summary (pp. 139–140) the quantities of radicles in milligrams per liter were obtained by such a calculation, the mean dissolved solids from the monthly analyses being taken as a basis of computation.

The accuracy of the monthly analyses has been checked by comparing the sum of the radicles with the total solids and the sum of the reacting values of the positive radicles with the sum of the reacting values of the negative radicles; apparently erroneous results that could not be corrected from the original notebooks have been discarded. In checking by reacting values it was found that most of the apparent percentage errors (found by dividing the algebraic sum by the arithmetical sum of the reacting values) were less than the value of the expression $3+\frac{1500}{\text{dissolved solids}}$, which was adopted as the maximum allowable error. The word "error" is here applied to apparent lack of closure in the chemical system of dissolved solids. The so-called error may result from undetermined radicles as well as from erroneous analytical results.

The following table shows the maximum error allowed by this expression for various amounts of dissolved solids:

Maximum allowable errors in reacting values.

Dissolved solids (milligrams per liter).	Error (per cent).	Dissolved solids (milligrams per liter).	Error (per cent).
80	21.7	360	7.3
90	19.7	400	6.8
100	18.0	450	6.3
110	16.6	500	6.0
120	15.5	600	5.5
130	14.5	700	5.1
140	13.7	800	4.9
150	13.0	900	4.7
160	12.4	1,000	4.5
180	11.3	1,200	4.2
200	10.5	1,500	4.0
220	9.8	2,000	3.8
240	9.2	5,000	3.3
260	8.8	7,500	3.2
300	8.0	15,000	3.1

The percentage errors in reacting values are shown in the tables of the analyses. The mean of the errors of analyses arranged by content of dissolved solids of the waters are given in the following table:

Mean errors of analyses of monthly composite samples.

Dissolved solids in milligrams per liter.	Number of analyses.	Mean error (per cent).
75 to 99 (mean 91)	16	10.0
100 to 149 (mean 123)	42	7.0
150 to 199 (mean 169)	39	5.9
200 to 299 (mean 247)	50	4.8
300 to 499 (mean 391)	81	3.7
500 to 999 (mean 730)	59	2.4
1,000 to 4,990 (mean 2,490)	73	1.8
5,000 to 21,600 (mean 9,600)	13	1.1

Some idea of the accuracy of the individual determinations may be gathered by considering the errors inherent in the methods of analysis employed. Titrations made in the ordinary way are all likely to be in error by 0.05 cubic centimeter of the solution and weighings are likely to be wrong by at least 0.5 milligram.

The following table shows the errors thus likely to be introduced into the tabulated analyses for the amounts of water and strengths of solutions generally used for the analyses. Errors greater than these are, of course, not unlikely through blunders in the analytical work, the table showing merely in a general way the minimum refinement probable in the work at Berkeley:

Errors likely to occur in individual analyses.

Determination or radicle.	Assumed error of analytical work.	Quantity of water used (cubic centimeters).	Resulting error in analysis (milligrams per liter).
Suspended matter	0.5 mg.	50	10
Do	0.5 mg.	100	5
Dissolved solids	0.5 mg.	50	10
Do	0.5 mg.	200	2.5
Calcium	0.5 mg.	200	1.8
Magnesium	0.5 mg.	200	.5
Sodium and potassium	0.5 mg.	200	1.0
Carbonate [a]	0.05 c. c.	50	2.3–3.2
Bicarbonate [a]	0.05 c. c.	50	2.4–3.3
Sulphate	0.5 mg.	200	1.0
Chlorine [a]	0.05 c. c.	50	2.3–5.0

[a] The range in resulting errors is due to the use of solutions of different strengths.

RESULTS AT SAMPLING STATIONS.

AMERICAN RIVER NEAR FAIROAKS, CAL.

Samples of water were collected from American River at Fairoaks Bridge, near Fairoaks, Cal., from July 9 to August 12, 1905, near the gaging station established by the United States Geological Survey November 3, 1904. Stream-flow data, including gage heights,

rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:

Water-Supply Papers: 134, pp. 145–146; 177, pp. 176–178; 213, pp. 146–147; 251, pp. 221–225.

Additional information in regard to the quality of the water of American River is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 41–43.

Partial analyses, gage heights, and rates of discharge of water and solids for American River at Fairoaks Bridge, near Fairoaks, Cal.

[Drainage area, 1,900 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.
1905.									
July 9, 10, 11, 12, 14, 15	0	47	9	92	80	2.15	815	202	176
July 16, 17, 18, 19	0	68	16	20	106	1.75	530	29	152
August 6, 7, 8, 9, 10, 11, 12	0	71	11	144	116	1.30	295	115	92

NOTE.—Analysis of a composite of the 17 daily samples collected between July 9 and August 12 gives dissolved solids 125 milligrams per liter; and radicles, in per cent of dissolved solids, as follows: Ca, 10; Mg, 3.8; Na+¾K, 18; CO_3, 0.00; HCO_3, 46; SO_4, 13; Cl, 10; and NO_3, 0.18; Na is 96 per cent of the Na+¾K and K is 6.3 per cent.

ANIMAS RIVER NEAR DURANGO, COLO.

Samples of water were collected from Animas River at a highway bridge near Durango, Colo., between March 19 and December 18, 1905. A gaging station was established at this bridge by the United States Geological Survey June 20, 1895, and was discontinued December 31, 1905. Stream-flow data, including gage heights, rating tables, and

estimates of discharge, for the station have been published by the Survey in the following reports:

Annual Reports: 18, IV, pp. 283–285; 19, IV, pp. 414–415; 20, IV, pp. 59, 379, 403; 21, IV, p. 301; 22, IV, p. 394.
Bulletin 140, pp. 198–200.
Water-Supply Papers: 11, p. 72; 16, p. 146; 28, pp. 132, 139, 142, 145; 38, pp. 310–311; 39, p. 452; 50, pp. 383–384; 52, p. 520; 66, pp. 97, 174; 74, p. 122; 85, pp. 35–37; 100, pp. 51–54; 133, pp. 183–186; 175, pp. 134–137.

BELLE FOURCHE RIVER NEAR BELLE FOURCHE, S. DAK.

Samples of water were collected from Belle Fourche River at a county bridge near Belle Fourche, S. Dak., between April 15, 1905, and June 23, 1906. A gaging station was established at this bridge by the United States Geological Survey May 26, 1903, and was discontinued June 23, 1906. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 99, pp. 57–59; 130, pp. 169–172; 172, pp. 156–159; 208, pp. 128–129.

Partial analyses, gage heights, and rates of discharge of water and solids for Belle Fourche River at county bridge near Belle Fourche, S. Dak.

[Drainage area, 3,250 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).

BELLE FOURCHE RIVER AT DIVERSION DAM NEAR BELLE FOURCHE, S. DAK.

Samples of water were collected from Belle Fourche River at the diversion dam of the United States Reclamation Service near Belle Fourche, S. Dak., between July 27 and November 13, 1906. A gaging station was established by the United States Geological Survey May 10, 1906, below the diversion dam and inlet canal of Belle Fourche project, United States Reclamation Service. Stream-flow data, including gage heights and estimates of discharge, for that point have been published by the Survey in the following report:

Water-Supply Paper 208, pp. 129–131.

Data from July, 1903, to June, 1906, may be obtained by adding discharge for Belle Fourche and Redwater rivers at Belle Fourche. See the following reports:

Annual Reports United States Reclamation Service: 3, pp. 488–489; 4, p. 325.
Water-Supply Papers: 99, pp. 57–60; 130, pp. 169–175; 172, pp. 156–161; 208, pp. 128–129, 131–132.

Partial analyses, gage heights, and rates of discharge of water and solids for Belle Fourche River at diversion dam near Belle Fourche.

BOISE RIVER NEAR BOISE, IDAHO.

Samples of water were collected from Boise River at Highland, near Boise, Idaho, between May 26, 1905, and April 30, 1907. A gaging station was established by the United States Geological Survey 9 miles above Boise December 15, 1894, and was removed to Highland, 8 miles upstream, in 1905. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for those points have been published by the Survey in the following reports:[a]

Annual Reports: 18, IV, pp. 340–344; 19, IV, pp. 452–454; 20, IV, p. 62, 483; 21, IV, pp. 411–412; 22, IV, 431–432.

Bulletins: 131, p. 66; 140, p. 236.

Water-Supply Papers: 11, p. 81; 16, p. 168; 28, pp. 155, 161, 168–169; 38, pp. 356–357; 39, p. 453; 51, pp. 427–428; 52, p. 522; 66, pp. 128, 176; 85, pp. 207–209; 100, pp. 436–439; 135, pp. 199–202; 178, pp. 121–123; 214, pp. 93–94; 252, pp. 245–248.

[a] See also Second Ann. Rept. U. S. Reclamation Service, p. 316.

Partial analyses, gage heights, and rates of discharge of water and solids for Boise River at Highland, near Boise, Idaho.

NOTE.—Gaging station removed 8 miles upstream to Highland early in 1905.

CARSON RIVER NEAR HAZEN, NEV.

Samples of water were collected from Carson River at the diversion dam of the United States Reclamation Service near Hazen, Nev., between April 10, 1906, and April 15, 1907. This dam is below the outlet of the canal carrying water from Truckee River to Carson River, and the samples taken during August, September, and Octo-

ber, 1906, represent a mixture of the waters of Truckee and Carson Rivers. The nearest gaging station of the United States Geological Survey is at Empire, Nev., about 60 miles above the diversion dam. The drainage area at Empire is 988 square miles and at the diversion dam is 1,700 square miles, but the flow is approximately the same at both places. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station at Empire have been published by the Survey in the following reports:[a]

Annual Report: 12, II, pp. 324–325.
Bulletin: 140, pp. 212–213.
Water-Supply Papers: 51, p. 401; 66, pp. 110–111, 175; 75, p. 189; 85, pp. 109–111; 100, pp. 175–177; 133, pp. 337–339; 176, pp. 111–113; 212, pp. 79–81; 250, p. 128.

Partial analyses of water from Carson River at diversion dam near Hazen, Nev.

[a] Approximate.
[b] From June, 1907, to March, 1908, the estimated flow of the river has been increased by 30 second-feet as a correction for the power-canal diversion. After the latter date the correction has been the measured flow of the canal.

COLORADO RIVER NEAR YUMA, ARIZ.

Samples of water were collected from Colorado River at the railroad bridge near Yuma, Ariz., between January 1 and December 30, 1905. A gaging station was established at the bridge by the Southern Pacific Company during the summer of 1876, and records of river height have been maintained since April 1, 1878. Stream-flow data, including gage heights, rating tables, and estimates of dis-

charge, for this station have been published by the Survey in the following reports:[a]

Annual Reports: 12, II, p. 290; 18, IV, pp. 298–299.
Bulletins: 131, pp. 51–52; 140, pp. 207–210.
Water-Supply Papers: 11, p. 73; 16, p. 151; 28, pp. 133, 141; 38, pp. 324–325; 50, p. 387; 66, p. 104; 81, pp. 69–71; 85, pp. 17–20; 100, pp. 19–25; 133, pp. 25–32; 177, pp. 13–16, 213, pp. 26–29; 249, pp. 41–46.

The results of other investigations of the quality of the Colorado River water at Yuma are reported as follows:

University of Arizona Agricultural Experiment Station: Bull. 44, The river irrigating waters of Arizona, by R. H. Forbes, 1902; Bull. 53, Irrigating sediments and their effects upon crops, by R. H. Forbes, 1906.
Third Annual Report United States Reclamation Service.

Partial analyses, gage heights, and rates of discharge of water and solids for Colorado River at railroad bridge near Yuma, Ariz.

[Drainage area, 225,000 square miles.]

ELM FORK OF RED RIVER NEAR MANGUM, OKLA.

Samples of water were collected from Elm Fork of Red River at a highway bridge near Mangum, Okla., between April 13, 1905, and March 22, 1907. A gaging station was established at the bridge by the United States Geological Survey April 12, 1905, and discontinued March 31, 1908. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for this station have been published by the Survey in the following reports:

Water-Supply Papers: 173, pp. 79–81; 209, pp. 57–59; 247, pp. 97–100.

Partial analyses, gage heights, and rates of discharge of water and solids for Elm Fork of Red River at highway bridge near Mangum, Okla.

[Drainage area, 750 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

Relative amount of substances in solution in water from Elm Fork of Red River at highway bridge near Mangum, Okla.

Limiting dates of composite.	Number of daily samples.	Errors.	Dissolved solids (Ds) (milligrams per liter).	Radicles in per cent of dissolved solids.							
				Calcium (Ca).	Magnesium (Mg).	Sodium and potassium ($Na+\frac{3}{4}K$).	Carbonate (CO_3).	Bicarbonate (HCO_3).	Sulphate (SO_4).	Chlorine (Cl).	Nitrate (NO_3).

FEATHER RIVER NEAR OROVILLE, CAL.

Samples of water were collected from Feather River near Oroville, Cal., between June 25, 1905, and February 14, 1907. A gaging station was established near Oroville by the United States Geological Survey January 1, 1902. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for this station have been published by the Survey in the following reports:

Water-Supply Papers: 66, p. 167; 81, pp. 85–87; 85, pp. 133–135; 100, pp. 272–274; 134, pp. 137–140; 177, pp. 155–158; 213, pp. 120–121; 251, pp. 199–202.

Additional information in regard to the quality of the water of Feather River is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 36–38.

Partial analyses, gage heights, and rates of discharge of water and solids for Feather River near Oroville, Cal.

[Drainage area, 3,640 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

GILA RIVER NEAR SAN CARLOS, ARIZ.

Samples of water were collected from Gila River near San Carlos, Ariz., between April 9, 1905, and January 20, 1906. A gaging station was established near San Carlos by the United States Geological Survey July 11, 1899, and was discontinued December 31, 1905. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for that point have been published by the Survey in the following reports:

Annual Reports: 21, IV, p. 332; 22, IV, pp. 397–398.

Water-Supply Papers: 33, p. 30; 38, pp. 313–314; 39, p. 452; 50, pp. 385–386; 52, p. 520; 66, pp. 98–99; 75, pp. 179–180; 85, pp. 32–35; 100, pp. 48–51; 133, pp. 199–204; 175, pp. 162–163.

Partial analyses and gage heights for Gila River near San Carlos, Ariz.

GRAND RIVER NEAR KREMMLING, COLO.

Samples of water were collected from Grand River at Gore Canyon near Kremmling, Colo., from April 23, 1905, to May 15, 1906. A gaging station was established at Gore Canyon by the United States Geological Survey July 24, 1904. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 133, pp. 137–139; 175, pp. 78–81; 211, pp. 69–71; 249 pp. 95–98.

Partial analyses, gage heights, and rates of discharge of water and solids for Grand River at Gore Canyon, near Kremmling, Colo.

[Drainage area, 2,380 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

GRAND RIVER NEAR PALISADE, COLO.

Samples of water were collected from Grand River at a highway bridge near Palisade, Colo., from March 15, 1905, to May 5, 1906. A gaging station was established near Palisade by the United States Geological Survey April 9, 1902. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Annual Reports: 19, IV, p. 401; 20, IV, pp. 378–389.
Water-Supply Papers: 85, pp. 46–48; 100, pp. 87–89; 133, pp. 142–144; 175, pp. 84–86; 211, pp. 74–75; 249, pp. 105–107.

Monthly discharge estimates for Grand River at Grand Junction, Colo., 12 miles below Palisade and below the headings of canals in the Grand Valley have been published as follows:[a]

Annual Reports: 19, IV, p. 401; 20, IV, pp. 378, 389; 21, IV, p. 281.
Water-Supply Papers: 74, pp. 130–131.

[a] See also Second Ann. Rept. U. S. Reclamation Service, pp. 215–216.

Partial analyses, gage heights, and rates of discharge of water and solids for Grand River at highway bridge near Palisade, Colo.

[Drainage area, 8,550 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

[a] Approximate.

GREEN RIVER NEAR JENSEN, UTAH.

Samples of water were collected from Green River at Billings ferry, near Jensen, Utah, from March 24, 1905, to May 11, 1906. A gaging station was established at the ferry by the United States Geological Survey November 7, 1903, and was discontinued October 31, 1906. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 100, pp. 123–124; 133, pp. 56–58; 175, p. 17; 211, pp. 26–28.

Partial analyses, gage heights, and rates of discharge of water and solids for Green River at Billings ferry, near Jensen, Utah.

[Drainage area, 26,600 square miles.]

GUNNISON RIVER NEAR WHITEWATER, COLO.

Samples of water were collected from Gunnison River at a State bridge near Whitewater, Colo., from April 2 to October 31, 1905. A gaging station was established at the bridge by the United States Geological Survey April 10, 1902, and was discontinued October 31, 1906. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Bulletin: 140, p. 189.

Water-Supply Papers: 16, p. 140; 66, pp. 94–95; 85, pp. 42–44; 100, pp. 64–67; 133, pp. 162–164; 175, pp. 112–115; 211, pp. 89–90.

Monthly discharge data for Gunnison River at Grand Junction, Colo.,[a] 8 miles below Whitewater, have been published by the Survey as follows:

Reports: 19, IV, p. 405; 20, IV, p. 390; 21, IV, p. 278.
Water-Supply Paper, 74, p. 134.

Partial analyses, gage heights, and rates of discharge of water and solids for Gunnison River at State bridge, near Whitewater, Colo.

HONDO RIVER NEAR ROSWELL, N. MEX.

Samples of water were collected from Hondo River at the United States Reclamation Service reservoir near Roswell, N. Mex., from March 26 to August 4, 1905. A gaging station was established at the reservoir by the United States Geological Survey March 9, 1903, and was discontinued March 31, 1908. Stream-flow data, including gage heights and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 99, pp. 362–363; 132, pp. 119–121; 174, pp. 118–120; 210. pp. 100–101; 248, pp. 137–138.

Partial analyses, gage heights, and rates of discharge of water and solids for Hondo River at reservoir near Roswell, N. Mex.

[Drainage area, 1,040 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

[a] March 16 to 31.

MALHEUR RIVER NEAR VALE, OREG.

Samples of water were collected from Malheur River at a highway bridge near Vale, Oreg., from March 26 to December 4, 1905. A gaging station was established at the bridge by the United States Geological Survey May 20, 1903, and gagings had been made at intervals since 1890. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Annual Reports: 11, II, pp. 88, 106; 12, II, pp. 344, 358, 361; 13, III, pp. 98–99; 18, IV, pp. 348–350; 20, IV, p. 62.

Bulletins: 92, p. 140; 131, p. 68; 140, pp. 242–243.

Water-Supply Papers: 11, p. 83; 16, p. 169; 100, pp. 424–427; 135, pp. 206–208; 178, pp. 126–129; 214, pp. 101–102; 252, pp. 257–259.

Partial analyses, gage heights, and rates of discharge of water and solids for Malheur River at highway bridge near Vale, Oreg.

[Drainage area, 4,860 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

NORTH FORK OF RED RIVER NEAR GRANITE, OKLA.

Samples of water were collected from North Fork of Red River at a railroad bridge near Granite, Okla., from April 12, 1905, to March 16, 1907. A gaging station was established at the bridge by the United States Geological Survey June 23, 1903, and was discontinued March 20, 1908. Stream-flow data, including gage heights and estimates of discharge, have been published by the Survey in the following reports:[a]

Water-Supply Papers: 99, pp. 319–320; 131, pp. 182–183; 173, pp. 73–75; 209, pp. 51–54; 247, pp. 89–92.

[a] See also Third Ann. Rept. U. S. Reclamation Service, p. 460.

Partial analyses, gage heights, and rates of discharge of water and solids for North Fork of Red River at railroad bridge near Granite, Okla.

[Drainage area, 2,210 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

[a] Approximate.

NORTH FORK OF RED RIVER NEAR HEADRICK, OKLA.

Samples of water were collected from North Fork of Red River at Navajo dam site near Headrick, Okla., from May 20, 1905, to March 19, 1907. A gaging station was established at the Frisco Railway bridge, 8 miles west of Snyder, by the United States Geological Survey, April 14, 1905, and was discontinued July 31, 1905; and a gaging station was established at Navajo dam site July 17, 1905, and discontinued March 30, 1908. Stream-flow data, including gage heights

and estimates of discharge, have been published by the Survey in the following reports:[a]

Water-Supply Papers: 173, pp. 75–78; 209, pp. 54–56; 247, pp. 93–96.

Partial analyses, gage heights, and rates of discharge of water and solids for North Fork of Red River at Navajo dam site, near Headrick, Okla.

[Drainage area, 5,470 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

[a] Approximate.

NORTH PLATTE RIVER NEAR FORT LARAMIE, WYO.

Samples of water were collected from North Platte River near Fort Laramie, Wyo., from May 21, 1906, to April 20, 1907. A gaging station was established by the United States Geological Survey at Guernsey, Wyo., about 15 miles above Fort Laramie, June 14, 1900. Stream-flow data, including gage heights, rating tables, and esti-

mates of discharge, for the gaging station have been published by the Survey in the following reports:

Annual Report 22, IV, 312.

Water-Supply Papers: 49, p. 275; 52, p. 516; 66, pp. 27, 171; 75, pp. 125-126; 84, pp. 68–70; 99, pp. 165–167; 131, pp. 35–38; 172, pp. 196–199; 208, pp. 142–144; 246, pp. 231–234.

Partial analyses, gage heights, and rates of discharge of water and solids for North Platte River near Fort Laramie, Wyo.

[Drainage area, 16,200 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

OWENS RIVER NEAR ROUND VALLEY, CAL.

Samples of water were collected from Owens River at a footbridge near Round Valley, Cal., from May 13, 1906, to April 27, 1907. A gaging station was established by the United States Geological Survey near Round Valley August 3, 1903. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:[a]

Water-Supply Papers: 100, pp. 206–207; 134, pp. 200–203; 177, pp. 50–52; 213, pp. 35–37; 251, pp. 53–55.

Additional information in regard to the quality of the water of Owens River near Round Valley is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 118–119.

[a] See also Third Ann. Rept., U. S. Reclamation Service, p. 200.

Partial analyses, gage heights, and rates of discharge of water and solids for Owens River at footbridge near Round Valley, Cal.

[Drainage area, 400 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

OWENS RIVER NEAR TINEMAHA, CAL.

Samples of water were collected from Owens River at the intake of the proposed Los Angeles aqueduct near Tinemaha, Cal., from November 6, 1906, to April 14, 1907. A gaging station was established near Tinemaha by the United States Geological Survey September 20, 1906, and measurements of the stream at this point were made previous to that date by the city of Los Angeles. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:

Water-Supply Papers: 213, pp. 38–39; 251, pp. 56–58.

Additional information in regard to the quality of the water of Owens River near Tinemaha is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 120–121.

Partial analyses, gage heights, and rates of discharge of water and solids for Owens River at the intake of the Los Angeles aqueduct, near Tinemaha, Cal.

Dates.	Analysis (milligrams per liter).										Gage height (feet).	Discharge (second-feet).	Solids (tons per day).

PALOUSE RIVER NEAR HOOPER, WASH.

Samples of water were collected from Palouse River near Hooper, Wash., from May 22 to October 8, 1905. A gaging station was established by the United States Geological Survey near Hooper April 1, 1897. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:

Annual Reports: 19, IV, p. 460; 20, IV, pp. 62, 489–490; 21, IV, pp. 414–415; 22, IV, p. 452.

Water-Supply Papers: 16, p. 172; 28, pp. 155, 162, 168, 170; 38, pp. 360–361; 39, p. 454; 51, pp. 443–444; 52, p. 522; 66, pp. 136–137, 177; 75, p. 206; 85, pp. 203–205; 100, pp. 413–415; 135, pp. 243–247; 178, pp. 171–173; 214, pp. 119–121; 252, pp. 281–283.

Partial analyses, gage heights, and rates of discharge of water and solids for Palouse River near Hooper, Wash.

[Drainage area, 2,210 square miles.]

PECOS RIVER AT CARLSBAD, N. MEX.

Samples of water were collected from Pecos River at Green Street, Carlsbad, N. Mex., from May 22, 1905, to April 30, 1907. A gaging station was established at Carlsbad by the United States Geological Survey May 20, 1903, and discontinued March 31, 1908. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:[a]

Water-Supply Papers: 99, pp. 358–360; 132, pp. 103–104; 174, pp. 102–105; 210, pp. 90–91; 248, pp. 125–126.

Further information relative to the quality of water of Pecos River at Carlsbad is contained in a paper entitled "Principles of water analysis," by Arthur Goss, in Bulletin 34, New Mexico Agricultural Experiment Station.

[a] See also Fourth Ann. Rept. U. S. Reclamation Service, pp. 271–272.

[a] Taken from Fourth Ann. Rept. U. S. Reclamation Service, p. 271. The figures represent the flow through the headgates and over the spillway at Avalon dam, but are approximately correct for Carlsbad.
[b] Approximate.

PECOS RIVER NEAR DAYTON, N. MEX.

Samples of water were collected from Pecos River below Penasco River near Dayton, N. Mex., from July 20, 1905, to April 20, 1907. A gaging station was established by the United States Geological Survey near Dayton March 24, 1905. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:

Water-Supply Papers: 174, pp. 99–101; 210, pp. 83–85; 248, pp. 119–122.

Partial analyses, gage heights, and rates of discharge of water and solids for Pecos River below Penasco River, near Dayton, N. Mex.

[Drainage area, 20,000 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

PECOS RIVER NEAR SANTA ROSA, N. MEX.

Samples of water were collected from Pecos River at a railroad bridge near Santa Rosa, N. Mex., between July 7, 1905, to December 29, 1906. A gaging station was established at the bridge by the United States Geological Survey May 5, 1903, and discontinued December 31, 1906. Stream-flow data, including gage heights and estimates of discharge, for the gaging station have been published by the Survey in the following reports:

Water-Supply Papers: 99, pp. 363–365; 132, pp. 97–98; 174, pp. 93–94; 210, pp. 78–79.

Partial analyses, gage heights, and rates of discharge of water and solids for Pecos River at railroad bridge near Santa Rosa, N. Mex.

[Drainage area 2,900 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

PIT RIVER NEAR BIEBER, CAL.

Samples of water were collected from Pit River at Muck Valley, near Bieber, Cal., from July 7, 1905, to March 2, 1907. A gaging station was established by the United States Geological Survey at Muck Valley January 22, 1904, and was discontinued October 1, 1908. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the gaging station have been published by the Survey in the following reports:

Water-Supply Papers: 134, pp. 134–137; 177, pp. 136–139; 213, pp. 104–105; 251, pp. 160–162.

Partial analyses, gage heights, and rates of discharge of water and solids for Pit River at Muck Valley, near Bieber, Cal.

[Drainage area, 2,950 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).

REDWATER RIVER NEAR BELLE FOURCHE, S. DAK.

Samples of water were collected from Redwater River at a county bridge near Belle Fourche, S. Dak., from April 9, 1905, to June 23, 1906. A gaging station was established near Belle Fourche by the United States Geological Survey July 20, 1903, and was discontinued June 23, 1906. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 99, pp. 59–60; 130, pp. 172–175; 172, pp. 160–161; 208, pp. 131–132.

Partial analyses, gage heights, and rates of discharge of water and solids for Redwater River at county bridge near Belle Fourche, S. Dak.

[Drainage area, 1,020 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

RIO GRANDE NEAR EL PASO, TEX.

Samples of water were collected from Rio Grande at Courchesne, near El Paso, Tex., from June 8, 1905, to April 30, 1907. A gaging station was established May 1, 1897, by the United States Geological Survey at Courchesne, 1 mile above the old station. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports: [a]

Annual Reports: 11, II, pp. 54, 57, 99; 12, II, pp. 280, 350, 360; 13, III, pp. 94, 99; 14, IV, 114–115; 18, IV, pp. 257–259; 19, IV, pp. 389–390; 20, IV, pp. 58, 358, 372; 21, IV, pp. 262–263; 22, IV, p. 353.

[a] See also Third Ann. Rept. U. S. Reclamation Service, p. 404.

Bulletins: 131, pp. 46–47; 140, pp. 178–179.

Water-Supply Papers: 11, p. 67; 16, pp. 132–133; 28, pp. 120, 128; 37, pp. 283–284; 50, pp. 352–353; 66, p. 70; 75, pp. 155–156; 84, pp. 181–183; 99, pp. 378–382; 132, pp. 67–71; 174, pp. 49–53; 210, pp. 55–57; 248, pp. 45–50.

Further information relative to the quality of water in the Rio Grande near El Paso is contained in Bulletin 34, New Mexico Agricultural Experiment Station, "Principles of water-analysis," by Arthur Goss, 1900.

Partial analyses, gage heights, and rates of discharge of water and solids for Rio Grande at Courchesne, near El Paso, Tex.

[b] Approximate.

RIO GRANDE NEAR SAN MARCIAL, N. MEX.

Samples of water were collected from Rio Grande at a railroad bridge near San Marcial, N. Mex., from May 28, 1905, to April 27, 1907. A gaging station was established by the United States Geological Survey near San Marcial January 29, 1895. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:[a]

Annual reports: 11, II, p. 107; 18, IV, pp. 254–257; 19, IV, pp. 387–389; 20, IV, pp. 58, 358, 371; 21, IV, p. 261; 22, IV, p. 352.

Bulletins: 131, p. 46; 140, pp. 177–178.

Water-Supply Papers: 11, p. 66; 16, p. 131; 28, pp. 120, 128, 129; 37, pp. 282–283; 50, pp. 351–352; 66, pp. 68–69; 75, p. 155; 84, pp. 183–186; 99, pp. 382–386; 132, pp. 62–67, 127; 174, pp. 43–48; 210, pp. 52–56; 248, pp. 40–45.

Partial analyses, gage heights, and rates of discharge of water and solids for Rio Grande at railroad bridge near San Marcial, N. Mex.

[Drainage area, 30,000 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

[a] Approximate.

SACRAMENTO RIVER NEAR RED BLUFF, CAL.

Samples of water were collected from Sacramento River at Iron Canyon, near Red Bluff, Cal., from July 3, 1905, to March 23, 1907. A gaging station was established by the United States Geological Survey at Jellys Ferry, 12 miles above Red Bluff, April 30, 1895, and moved to a point in Iron Canyon, 4 miles above Red Bluff, in 1902. The drainage area at the upper point is 9,130 square miles and at the lower point 9,300 square miles. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:[a]

Annual Reports: 18, IV, pp. 365–369; 19, IV, pp. 509–510; 20, IV, pp. 63, 527; 21, IV, pp. 446–447; 22, IV, p. 462.

Bulletin: 140, pp. 250–252, 254.

Water-Supply Papers: 11, p. 89; 16, pp. 185–186; 28, pp. 177, 182, 185–186; 38, pp. 387–389; 39, p. 455; 51, pp. 450–451; 52, p. 523; 66, pp. 142–143, 167, 177; 75, p. 210; 81, pp. 191–198; 85, pp. 137–141; 100, pp. 278–280; 134, pp. 118–122; 177, pp. 128–130; 213, pp. 101–102; 251, pp. 154–157.

SACRAMENTO RIVER AT SACRAMENTO, CAL.

Samples of water were collected from Sacramento River at Sacramento, Cal., from May 29 to December 29, 1905. A gaging station is maintained on the Sacramento River at Sacramento, and daily gage heights are published by the United States Weather Bureau. United States Geological Survey Water-Supply Paper 134, pages 146 and 147, contains daily gage heights and turbidity for 1904, and Water-Supply Paper 177, page 131, contains gage heights for the first half of 1905. The monthly discharge of Sacramento River at Collinsville, Cal. (about one-quarter greater than the discharge at Sacramento), from 1878 to 1884 is contained in Water-Supply Paper 81, pages 188–190.

Additional information in regard to the quality of the water of Sacramento River at Sacramento is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 30–32.

SALMON CREEK NEAR MALOTT, WASH.

Samples of water were collected from Salmon Creek at the Jones house, near Malott, Wash., from May 23, 1905, to January 13, 1906. A gaging station was established by the United States Geological Survey near Malott, April 11, 1903. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports: [a]

Water Supply Papers: 100, pp. 389–392; 135, pp. 63–65; 178, pp. 32–34; 214, p. 33; 252, pp. 122–124.

Partial analyses, gage heights, and rates of discharge of water and solids for Salmon Creek at Jones house, near Malott, Wash.

SALT RIVER NEAR ROOSEVELT, ARIZ.

Samples of water were collected from Salt River at a dam site near Roosevelt, Ariz., from April 9, 1905, to April 23, 1906. A gaging station was established by the United States Geological Survey on Salt River at the reservoir site February 7, 1901, and was discontinued December 9, 1907. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:[a]

Water-Supply Papers: 66, pp. 99–100; 73, pp. 26–29; 75, p. 178; 85, pp. 25–29; 100, pp. 42–45; 133, pp. 212–214; 175, pp. 173–177; 211, pp. 130–133; 249, pp. 183–186.

[a] See also First Ann. Rept. U. S. Reclamation Service, p. 93.

Information relative to the quality of Salt River near McDowell, Ariz., below the mouth of Verde River is contained in Bulletin 44, University of Arizona Agricultural Experiment Station, "The river irrigating waters of Arizona," by R. H. Forbes, 1902.

Partial analyses, gage heights, and rates of discharge of water and solids for Salt River at dam site near Roosevelt, Ariz.

[a] Proportional part of discharge of Salt River at Arizona Dam.
[b] Approximate.
[c] Proportional discharge of Salt River at McDowell.

SALT FORK OF RED RIVER NEAR MANGUM, OKLA.

Samples of water were collected from Salt Fork of Red River near Mangum, Okla., from April 11, 1905, to June 28, 1906. A gaging station was established by the United States Geological Survey near Mangum April 11, 1905, and was discontinued June 30, 1906. Stream-flow data, including gage heights and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 173, pp. 91–93; 209, pp. 67–68.

Partial analyses, gage heights, and rates of discharge of water and solids for Salt Fork of Red River at highway bridge near Mangum, Okla.

[Drainage area, 1,220 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).	Mean discharge (second-feet).	Solids (tons per day).	
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).			Suspended matter.	Dissolved solids.

SAN FRANCISCO RIVER NEAR ALMA, N. MEX.

Samples of water were collected from San Francisco River near Alma, N. Mex., from April 14, 1905, to April 22, 1906. A gaging station was established by the United States Geological Survey near Alma, October 18, 1904, and was discontinued December 31, 1907. Stream-flow data, including gage heights and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 133, pp. 206–208; 175, pp. 166–170; 211, pp. 125–128; 249, pp. 177–180.

Partial analyses, gage heights, and rates of discharge of water and solids for San Francisco River near Alma, N. Mex.

[Drainage area, 1,800 square miles.]

SAPELLO RIVER NEAR LOS ALAMOS, N. MEX.

Samples of water were collected from Sapello River at a ford near Los Alamos, N. Mex., from March 19, 1905, to April 5, 1906. A gaging station was established by the United States Geological Survey near Los Alamos, N. Mex., August 22, 1903. Stream-flow data, including gage heights and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 99, pp. 249–250; 131, pp. 166–168; 173, pp. 63–64; 209, p. 44; 247, pp. 79–82.

Partial analyses of water of Sapello River at ford near Los Alamos, N. Mex., with gage heights.

[Drainage area, 200 square miles.]

Dates.	Analysis (milligrams per liter).					Mean gage height (feet).
	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Chlorine radicle (Cl).	Suspended matter (Sm).	Dissolved solids (Ds).

SHOSHONE RIVER NEAR CODY, WYO.

Samples of water were collected from Shoshone River at a wagon bridge near Cody, Wyo., from April 2, 1905, to March 30, 1906. A gaging station was established near Cody by the United States Geological Survey April 26, 1902. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 84, pp. 21–23; 99, pp. 83–85; 130, pp. 132–136; 172, pp. 113–115; 208, pp. 103–105; 246, pp. 194–197.

Partial analyses, gage heights, and rates of discharge of water and solids for Shoshone River at wagon bridge near Cody, Wyo.

STONY CREEK NEAR FRUTO, CAL.

Samples of water were collected from Stony Creek at the Julian ranch, near Fruto, Cal., from September 14, 1905, to January 13, 1906. A gaging station was established near Fruto by the United States Geological Survey January 30, 1901. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 66, pp. 143–144, 178; 75, p. 211; 81, pp. 341–342; 85, pp. 135–137; 100, pp. 274–276; 134, pp. 116–118; 177, pp. 153–155; 213, pp. 108–109; 251, pp. 170–173.

Partial analyses, gage heights, and rates of discharge of water and solids for Stony Creek at Julian ranch, near Fruto, Cal.

[Drainage area, 760 square miles.]

[a] Approximate.

TRUCKEE RIVER NEAR DERBY, NEV.

Samples of water were collected from Truckee River at the Reclamation Service diversion dam near Derby, Nev., from April 10, 1906, to March 13, 1907. A gaging station was established by the United States Geological Survey at Vista, Nev., August 18, 1899, and was moved to Derby, Nev., about 15 miles downstream, in 1907. The drainage area is 1,520 square miles at Vista. The flow is practically the same at both points. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:[a]

Annual Reports: 11, II, p. 102; 12, II, pp. 324, 351; 13, III, pp. 95, 99; 20, IV, p. 59; 22, IV, p. 405.

Water-Supply Papers: 38, pp. 331–332; 51, pp. 404–405; 52, p. 521; 66, pp. 113–114, 175; 81, pp. 371–373; 85, pp. 117–119; 100, pp. 185–187; 133, pp. 301–303; 176, pp. 84–86; 212, pp. 67–68; 250, pp. 111–112

[a] See also Second Ann. Rept. U. S. Reclamation Service, p. 358; Third Ann. Rept., p. 346.

Partial analyses, gage heights, and rates of discharge of water and solids for Truckee River at diversion dam near Derby, Nev.

[Drainage area, 1,750 square miles.]

TUOLUMNE RIVER NEAR LA GRANGE, CAL.

Samples of water were collected from Tuolumne River at a wagon bridge near La Grange, Cal., from October 7, 1905, to January 3, 1906. A gaging station was established by the United States Geological Survey near La Grange August 29, 1895. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Annual Reports: 18, IV, pp. 378–383; 19, IV, pp. 512–514; 20, IV, pp. 63, 532; 21, IV, pp. 449–450, 454; 22, IV, p. 465.

Bulletin 140, pp. 301–303.

Water-Supply Papers: 11, p. 90; 16, p. 188; 28, pp. 178–179, 183–186; 38, pp. 393–395; 39, p. 455; 66, pp. 149, 167, 178; 75, p. 214; 81, pp. 386–392; 85, pp. 142–145; 100, pp. 285–287; 134, pp. 156–158; 177, pp. 209–212; 213, pp. 165–169; 251, pp. 270–280.

Additional information in regard to the quality of the water of Tuolumne River is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 51–53.

NOTE.—No flow in Modesto canal until 1903. Not included in table is flow of La Grange Ditch and Hydraulic Mining Company's canal with following approximate discharge in second-feet: 1895, 35; 1896, 32; 1897–1899, 24; 1900, 20; 1901–1908, less than 10. The Tuolumne was gaged at Modesto, a short distance below La Grange, by the state engineer, from November, 1878, to October, 1884, and by the U. S. Geological Survey in 1895 and 1896. Monthly discharge for these periods is published in Water-Supply Paper 81, pp. 396–399; the monthly mean discharge is given below.

Monthly discharge, in second-feet, of Tuolumne River near Modesto, Cal.

TURKEY CREEK NEAR OLUSTEE, OKLA.

Samples of water were collected from Turkey Creek at Fullerton dam, near Olustee, Okla., from March 4, 1906, to February 19, 1907. A gaging station was established by the United States Geological

Survey at Olustee April 20, 1905. Stream-flow data, including gage heights and estimates of discharge, for the station have been published by the Survey in the following reports:

Water-Supply Papers: 173, pp. 94–95; 209, p. 69; 247, pp. 86–88.

VERDE RIVER NEAR McDOWELL, ARIZ.

Samples of water were collected from Verde River at Mesa, near McDowell, Ariz., from April 5, 1905, to March 10, 1906. A gaging station was established by the United States Geological Survey near McDowell, Ariz., April 20, 1897. Stream-flow data, including gage

heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:[a]

Annual Reports: 11, II, p. 100; 19, IV, pp. 420–423; 20, IV, pp. 59, 407; 21, IV, pp. 387–388.
Bulletin 131, pp. 49, 51.
Water-Supply Papers: 16, p. 150; 28, pp. 133, 141, 143; 38, pp. 323–324; 50, p. 387; 66, pp. 102–103; 73, pp. 13–16; 75, p. 177; 85, pp. 21–23; 100, pp. 31–36; 133, pp. 222–227; 175, pp. 181–185; 211, pp. 137–139; 249, pp. 191–195.

Information relative to the quality of Salt River at McDowell, below the mouth of Verde River, is contained in Bulletin 44 of the University of Arizona Agricultural Experiment Station, "The river irrigating waters of Arizona," by R. H. Forbes, 1902.

Partial analyses, gage heights, and rates of discharge of water and solids for Verde River at Mesa, near McDowell, Ariz.

YELLOWSTONE RIVER NEAR BILLINGS, MONT.

Samples of water were collected from Yellowstone River at a county bridge near Billings, Mont., from May 20 to November 24, 1905. A gaging station was established by the United States Geological Survey near Billings May 29, 1904, and was discontinued December 31, 1905. A station was established at Junction May 10, 1906, and was discontinued December 31, 1907; and a station was then established at Huntley, Mont., January 1, 1907. The flow at the three stations is approximately the same. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for these stations have been published by the Survey in the following reports:

Water-Supply Papers: 130, pp. 120–122; 172, pp. 95–97; 208, pp. 88–90; 246, pp. 144–148.

Partial analyses, gage heights, and rates of discharge of water and solids for Yellowstone River at county bridge near Billings, Mont.

YELLOWSTONE RIVER NEAR GLENDIVE, MONT.

Samples of water were collected from Yellowstone River at a highway bridge near Glendive, Mont., from March 28, 1905, to April 21, 1906. A gaging station was established near Glendive in 1893, and gage heights recorded by the United States Weather Bureau. The records of the United States Geological Survey begin August 1, 1903. Stream-flow data, including gage heights, rating tables, and estimates of discharge for the station have been published by the Survey in the following reports:

Water-Supply Papers: 99, pp. 91–97; 130, pp. 123–126; 172, pp. 97–100; 208, pp. 90–92; 246, pp. 149–150.

Partial analyses, gage heights and rates of discharge of water and solids for Yellowstone River at highway bridge near Glendive, Mont.

YUBA RIVER NEAR SMARTSVILLE, CAL.

Samples of water were collected from Yuba River at the narrows near Smartsville, Cal., from July 7 to September 7, 1905. A gaging station was established by the United States Geological Survey near Smartsville, June 2, 1903. Stream-flow data, including gage heights, rating tables, and estimates of discharge, for the station have been published by the Survey in the following reports:

Annual Report 22, IV, p. 463.

Water-Supply Papers: 51, pp. 452–453; 85, p. 157; 100, pp. 270–272; 134, pp. 140–143; 177, pp. 160–164; 213, pp. 141–143; 251, pp. 213–216.

Additional information in regard to the quality of the water of Yuba River is contained in Water-Supply Paper 237, "Quality of California surface waters," pages 38–41.

Partial analyses, gage heights, and rates of discharge of water and solids for Yuba River at the narrows near Smartsville, Cal.

[a] Calculated from dissolved solids in milligrams per liter and radicles in per cent of dissolved solids.
[b] Including carbonates calculated as HCO_3.
[c] See pp. 11–12.

Summary of results of mineral analyses of surface waters of western United States—Continued.

Source (river unless otherwise stated) and location.	Dissolved solids (Ds) (milligrams per liter).	Radicles in milligrams per liter.							Radicles in per cent of dissolved solids.							Reacting values of radicles.							
		Calcium (Ca).	Magnesium (Mg).	Sodium and potassium ($Na+\frac{3}{4}K$).	Bicarbonate (HCO_3).	Sulphate (SO_4).	Chlorine (Cl).	Nitrate (NO_3).	Calcium (Ca).	Magnesium (Mg).	Sodium and potassium ($Na+\frac{3}{4}K$).	Bicarbonate (HCO_3).	Sulphate (SO_4).	Chlorine (Cl).	Nitrate (NO_3).	Calcium (Ca).	Magnesium (Mg).	Sodium and potassium ($Na+\frac{3}{4}K$).	Bicarbonate (HCO_3).	Sulphate (SO_4).	Chlorine (Cl).	Nitrate (NO_3).	Apparent error (per cent).

MISCELLANEOUS ANALYSES.

In addition to the series of analyses of stream waters, analyses of waters from streams, lakes, springs, wells, and borings were made from time to time at the Berkeley laboratory. These analyses are included under appropriate headings in the tables following.

Miscellaneous stream analyses.

State.	Location.	Stream.	Date.	Analysis (milligrams per liter).								Suspended matter (tons per day).	Dissolved solids (tons per day).	Gage height (feet).	Discharge (second-feet).
				Calcium radicle (Ca).	Magnesium radicle (Mg).	Sodium and potassium radicles ($Na+\frac{3}{4}K$).	Carbonate radicle (CO_3).	Bicarbonate radicle (HCO_3).	Sulphate radicle (SO_4).	Chlorine radicle (Cl).	Nitrate radicle (NO_3).

ANALYSES OF SUSPENDED MATTER.

Colorado River and the Rio Grande carry more matter in suspension than do most other streams in the United States. The nature of this suspended matter and its fertilizing value are of special interest. Analyses of the mineral matter carried by these two streams were made at various times in 1905. The results of plant food analyses, by the method of the Association of Official Agricultural Chemists, and the ultimate composition of the suspended matter obtained by the fusion method are presented in the following tables:

Analyses of suspended matter in water from Colorado River and the Rio Grande in 1905.

Organic and volatile matter	6.34	8.32

SEDIMENT CARRIED BY THE RIO GRANDE.

By HERMAN STABLER.

BASIC DATA.

The following study of the sediment carried by the Rio Grande is based on (1) measurements made at San Marcial, N. Mex., by the International Boundary Commission and published by the United States Geological Survey; and (2) determinations of silt, by weight, made for the Reclamation Service in the laboratory at Berkeley, Cal., under the direction of T. H. Means and W. H. Heileman.

The stream measurements and computations of flow were made in accordance with the usual methods for shifting channels, and reliable results are available for the 12 years beginning with 1897. The analytical results were developed from determinations, by the indirect method, of the weight of suspended matter in samples collected for the most part twice a week from the Rio Grande at San Marcial, N. Mex., from May 28, 1905, to April 27, 1906.

TABULATED ESTIMATES.

In Table 1 are presented the daily discharge of water, in acre-feet (obtained by multiplying the published discharge in second-feet by 2); the actual individual determinations of per cent, by weight, of suspended matter; estimates of the per cent, by volume, of sediment for each day (made from the basic data on the assumption that 85 pounds of suspended matter will make a cubic foot of sediment); and estimates of the daily discharge, in acre-feet, of sediment.

[a] The daily discharge in acre-feet was obtained by taking twice the recorded discharge in second-feet, and the values are therefore a little over 1 per cent too large. The monthly totals are the values reported by the Geological Survey.

This table indicates that, though the usual rule of variation of per cent of sediment directly with discharge may hold for a few consecutive days, when the results for a long period are considered the stage of the river and the proportion of sediment exhibit no constant relation. This is readily accounted for by the influence of different tributaries, the abnormal effects of storms in the arid catchment area, and particularly by the influence of the Rio Puerco, which at times carries into the Rio Grande at low stage a flood of heavily silt-laden waters. Certain seasonal variations of the sediment-to-water ratio are noticeable, but they are not sufficiently well defined to be expressed in any simple mathematical law.

Monthly summaries of water and sediment discharged and of the sediment-water ratio are given in Table 2.

TABLE 2.—*Monthly discharge of water and sediment in acre-feet and sediment-water ratio in per cent for the Rio Grande at San Marcial, New Mexico.*

Month.	1905–6.			1906–7.

February	39,689	142	.357	67,696	175	.258
March	56,866	246	.432	92,549	307	.332
April	163,140	1,339	.821	222,863	796	.358

Two years ending April 30, 1907:		
Water	acre-feet	3,829,210
Sediment	do	17,020
Ratio	per cent	0.445
Mean of all sediment determinations (0.853 by weight)	do	.626

Although many of the eccentricities of the daily results are smoothed out in the monthly summaries, there still seems to be no relation between discharge of water and sediment that should be taken for general application. For the entire period of two years the mean sediment-to-water ratio, by volume, is 0.445 per cent. It is believed that this ratio may be applied to the annual discharge in finding the quantity of sediment for any year, with errors due to variation of sediment-water ratio as follows:

Discharge 1,000,000 acre-feet or greater, error not to exceed 50 per cent.
Discharge less than 1,000,000 acre-feet, error not to exceed 100 per cent.

The difference between the ratios 0.445 and 0.626 shown at the bottom of Table 2 affords an excellent illustration of the great errors that are likely to occur in estimates based on the product of mean values for discharge and sediment rather than on the mean of products of discharge and sediment.

During the period for which records are available nearly 80 per cent of the discharge has occurred in years when the flow was more than 960,000 acre-feet. It is therefore stated with a considerable degree of assurance that the use of the ratio 0.445 per cent introduces an error for the period much less than 50 per cent and that an allowance of 50 per cent will cover all errors of observations, assumptions, and meager data. The mean annual flow of the Rio Grande at San Marcial for 12 years beginning with 1897 is 1,138,377 acre-feet (see Table 5, p. 162). Using the above-mentioned ratio, the mean annual sediment discharge for the same period would be 5,070 acre-feet. It is interesting to note that a calculation from the mean of the sediment observations would give results about 40 per cent greater.

THEORETICAL EXTENSION OF ESTIMATES.

The discharge of water and the sediment-to-water ratio for various yearly periods within the two years covered by sediment observations are presented in Table 3. A marked tendency toward decrease of ratio with increase of water discharge is evident. By plotting these values and drawing a straight line through the points it was found that all the ratios scaled from the graph were within 9 per cent of those in Table 3, whereas the mean ratio, 0.445 per cent, varies nearly 25 per cent from one of the ratios in Table 3. A considerable increase in accuracy would therefore seem to be secured by use of the graph.

TABLE 3.—*Annual discharge of water and sediment in acre-feet and sediment-water ratio in per cent for the Rio Grande at San Marcial, New Mexico.*

Year ending—	Water.	Sediment.	Ratio.
1906.			
April 30	2,117,921	9,030	0.427
May 31	1,656,407	8,120	.491
June 30	1,287,203	6,750	.525
July 31	1,369,735	7,220	.527
August 31	1,392,852	7,230	.520
September 30	1,413,103	8,330	.590
October 31	1,476,584	8,670	.588
November 30	1,511,939	8,310	.550
December 31	1,563,737	8,460	.541
1907.			
January 31	1,587,876	8,440	.532
February 28	1,615,883	8,470	.525
March 31	1,651,566	8,540	.517
April 30	1,711,289	7,990	.467

TABLE 4.—*Sediment-water ratios for various values of annual discharge.*

Annual discharge.	Ratio (per cent).	Annual discharge.	Ratio (per cent.)	Annual discharge.	Ratio (per cent).
1,000,000 acre-feet	0.621	1,500,000 acre-feet	0.536	2,000,000 acre-feet	0.449
1,100,000 acre-feet	.604	1,600,000 acre-feet	.518	2,100,000 acre-feet	.431
1,200,000 acre-feet	.587	1,700,000 acre-feet	.500	2,200,000 acre-feet	.414
1,300,000 acre-feet	.569	1,800,000 acre-feet	.483	2,300,000 acre-feet	.387
1,400,000 acre-feet	.552	1,900,000 acre-feet	.466	2,400,000 acre-feet	.380

Table 4 presents the ratios scaled from the graph corresponding to various values for annual discharge. This table covers about 80 per cent of the recorded annual discharge and is apparently correct within 10 per cent for individual years. The data do not warrant extension of the graph to include low-flow years, but it is interesting to note that an extension as a straight line would give a ratio of 0.76 per cent for a discharge of 200,000 acre-feet, which is the minimum recorded annual flow.

Based on Table 4 is the following estimate of the annual discharge of sediment for 12 years, shown in Table 5.

TABLE 5.—*Annual discharge of water in acre-feet, annual discharge of sediment in acre-feet based on the ratios of table 4, and annual discharge of sediment in acre-feet calculated from the ratio 0.445 per cent.*

Year.	Water.	Sediment from ratios of Table 4.	Sediment from ratio 0.445 per cent.
1897	2,215,257	9,080	9,850
1898	964,677	6,070	4,290
1899	239,835	[a] 1,910	1,070
1900	484,324	[a] 3,870	2,160
1901	656,274	[a] 5,250	2,920
1902	200,729	[a] 1,610	890
1903	1,278,069	7,380	5,660
1904	709,796	[a] 5,670	3,160
1905	2,422,008	9,160	10,800
1906	1,563,737	8,130	6,950
1907	2,157,709	9,050	9,590
1908	774,109	[a] 6,190	3,450
Total	13,660,524	73,370	60,790
Mean	1,138,377	6,110	5,070

[a] Ratio 0.8 per cent used.

For comparison, the sediment as calculated from the ratio 0.445 per cent is also shown. In obtaining the values in column 3 for discharges not included in Table 4, the single ratio 0.8 per cent has been used. This ratio seems to be a fair one for the low-flow years and is doubtless not more than 50 per cent in error. Inasmuch as it affects but 20 per cent of the entire flow for the 12 years, this ratio can not introduce an error of more than about 10 per cent in the mean annual sediment discharge for the period—6,110 acre-feet. It is believed that this mean, which corresponds to a mean annual sediment-to-water ratio of 0.536 per cent, is within 25 per cent of the actual for any long term of years after allowing for all errors.

ACCURACY OF DATA AND ESTIMATES.

The mean monthly values for discharge of water are probably not in error by more than 10 or 15 per cent. The sediment determinations are probably equally accurate. The chief opportunity for error

is owing to the fact that the samples used for sediment determinations do not include material rolled along the bottom of the stream and that a single sample will not represent the true mean condition for the entire cross section. Data on the error so introduced are meager, but the preponderance of evidence indicates that it is not more than 10 per cent. Opinions have frequently been expressed placing the error as high as 50 per cent, but observations available do not support them. The errors of observation, both on stream gaging and sediment determinations, are likely to offset one another, except for the omission of material rolled along the bottom of the stream. There seems to be reason therefore to believe that the monthly averages of the silt carried and of the water-to-sediment ratio are likely to be correct within 10 or 15 per cent. The yearly results and those for the entire period of 2 years may reasonably be expected to be still more accurate.

The error in assuming that the conditions for 2 years may be applied to those of 12 years, and that those of 12 years may be applied to hundreds of years is problematical. The mean annual flow for the 12 years differs by a maximum of about 33 per cent from the mean of any 6 years for which flow records are available, but by less than 26 per cent from the mean of any 8 years and by less than 11 per cent from the mean of any 9 years. Successions of low-flow years and series of high-flow years are included and it is to be expected that the cycle of changes in flow is fairly complete. In a catchment area so large and subject to normal arid conditions there is always, however, the possibility of abnormal conditions for a few years overthrowing even long-term averages.

The assumption that 85 pounds of suspended matter will produce a cubic foot of sediment may introduce an error. When newly deposited as little as 50 pounds of sediment may occupy a cubic foot of space.[a] At the other extreme it may require 120 pounds of compact dry earth to make a cubic foot. The value 85 pounds to the cubic foot may therefore be in error in individual cases by as much as 40 per cent. When sediment is compacted through a long term of years and is subject to alternate wet and dry conditions, however, the limits of weight and volume are greatly reduced. The value 85 pounds to the cubic foot supposes voids of 48 per cent and a weight of wet sediment of 115 pounds to the cubic foot. It corresponds to the commonly accepted value for weight of mud and dredged material and is probably not more than 15 per cent in error for long-term sediment deposits in any large reservoir in the United States.

[a] See sediment estimates for Rio Grande in Third Ann. Rept. U. S. Reclamation Service.

ROCK MATTER, SOIL, AND SEDIMENT.

In the foregoing discussion 6,110 acre-feet was estimated as the probable mean annual discharge of sediment for the Rio Grande for any long term of years. This estimate relates particularly to reservoir filling capacity, being based on the assumption that 85 pounds of suspended matter will occupy a cubic foot of space. However, if reduced to the state of rock matter, about 165 pounds would be required to fill a cubic foot; if reduced to the state of soil matter, about 100 pounds would be required; and if expanded to the state of freshly-deposited sediment, only about 60 pounds would be required. The probable mean annual discharge for a long term of years may therefore be variously expressed as representing 11,300,000 tons of suspended matter, 3,150 acre-feet of rock matter, 5,200 acre-feet of soil, 6,110 acre-feet of compacted sediment, or 8,650 acre-feet of freshly deposited sediment.

THE INDUSTRIAL APPLICATION OF WATER ANALYSES.[a]

By Herman Stabler.

Recent practice among water analysts tends toward the statement of analyses in ionic form, in parts per million, and the abolition of the statement in grains per gallon of mineral salts supposed to be present. The interpretation of the analysis can be made from either form of statement without great difficulty. The newer form, although admittedly better in many respects than the old, is, nevertheless, comparatively unfamiliar to many, and its interpretation is consequently somewhat obscure. Herewith are presented a few simple calculations and formulas which will assist in clearing up this obscurity and enable one not well grounded in chemical nomenclature to interpret and compare analyses expressed in ionic form, in parts per million, and to classify waters for industrial purposes. The calculations and formulas presented relate to the soap consuming power of water, to water softening, and to the interpretation of analyses with respect to the use of water in boilers and for irrigation, and may be readily enlarged in scope to include all industrial water problems.

THE ANALYSIS.

A mineral analysis of waters such as are ordinarily used for industrial purposes includes four classes of water impurities—suspended matter, colloidal matter, dissolved solids, and dissolved gases.

Suspended matter includes all organic or inorganic matter that can be removed by filtering. It is of a complex nature and consists of many chemical compounds which are not usually determined in detail. Two determinations relating to suspended matter are often made. The first is turbidity (Tu), the figures for which indicate the number of parts per million of a known standard suspended matter that will be just as cloudy or obscure just as much light as the water under consideration. The second is suspended matter (Sm) and represents the actual weight of the suspended matter in the water. If the particles in suspension are very fine, a comparatively small

[a] Revision of an article printed in the Engineering News, vol. 60, p. 355, 1908.

weight will produce a high turbidity. The ratio of turbidity to suspended matter, therefore, is a measure of the average weight or size of the particles in suspension. This ratio is called the coefficient of fineness (Fi).

$$(1)\ Fi = \frac{Tu}{Sm}$$

The greater the value of this coefficient the greater will be the average weight of the suspended particles, and hence the greater will be the ease with which they can be removed.

Colloidal matter includes, for the most part, silica (SiO_2), alumina (Al_2O_3), and iron oxide (Fe_2O_3), though in polluted waters and in some normal waters a considerable amount of organic matter may be present in the colloidal state. This material is present in a state intermediate between suspension and true solution. In the mineral analysis it is not distinguished as such; but the three mineral components above mentioned are determined separately, as though present in solution. There is always some doubt as to whether the silicon, aluminum, and iron are actually present as oxides in the colloidal state or as radicles in true solution. Silicon is rarely, if ever, present in true solution; aluminum forms a part of the system of dissolved solids only in acid waters; and iron is in true solution chiefly in ground waters, and then only in small quantity except in acid waters. In this article the iron and aluminum are included both in the dissolved and colloidal matter in order that both possible occurrences may be covered; but the silicon, because of its very rare occurrence in appreciable quantity in any other form, is included only under the head of colloidal matter. As stated later, the individual analysis may indicate definitely the state of these substances; but it is a safe rule to consider them as being present in the colloidal state. The term "colloidal matter," as here used, means the oxides of silicon, iron, and aluminum and will be designated Cm.

Dissolved gases (Dg) are not determined in many analyses. Oxygen (O), nitrogen (N), and carbon dioxide (CO_2) are generally present in water, and hydrogen sulphide (H_2S) and a few other gases are not unusual. Of these carbon dioxide is most important industrially and will alone be considered, expressed in parts per million.

Dissolved solids (Ds), as here used, refers to the mineral solids actually dissolved in the water. The usual determinations included under this term are iron (Fe), aluminum (Al), calcium (Ca), magnesium (Mg), sodium (Na), potassium (K), acidity (H), carbonate radicle (CO_3), bicarbonate radicle (HCO_3), sulphate radicle (SO_4), chlorine (Cl), and nitrate radicle (NO_3). Acidity is variously reported as hydrochloric acid (HCl), sulphuric acid (H_2SO_4), calcium carbonate ($CaCO_3$), and hydrogen (H). It is here expressed as hydrogen

and may be converted to this form from the others by the following factors:

$$H = .0276\ HCl = .0206\ H_2SO_4 = .0202\ CaCO_3.$$

The first seven of these are called positive radicles and the remaining five negative radicles. Taken together the twelve constitute a chemical system of positive and negative radicles (which may or may not be in actual combination), each of which has the power to react with or hold in the system a definite weight of radicles of the opposite sign. This power will be designated the "reaction coefficient" (r) of that radicle. The reaction coefficient may be defined as the ratio of the capacity for reaction to the weight of a chemical substance, and therefore represents the capacity for reaction of a unit weight of the substance. It is measured in more commonly used terms by the ratio of the valence to the atomic weight of the radicle.

(2) Reaction coefficient, $r = \frac{\text{valence}}{\text{atomic weight}}$

The division into positive and negative radicles and the reaction coefficients of the radicles as used in calculating the international atomic weights of 1909 are as follows:

Positive radicles.	Reaction coefficients.	Negative radicles.	Reaction coefficients.
Ferrous iron (Fe)	0.0358	Carbonate (CO_3)	0.0333
Aluminum (Al)	.1107	Bicarbonate (HCO_3)	.0164
Calcium (Ca)	.0499	Sulphate (SO_4)	.0208
Magnesium (Mg)	.0822	Chlorine (Cl)	.0282
Sodium (Na)	.0435	Nitrate (NO_3)	.0161
Potassium (K)	.0256		
Hydrogen (H)	.992		

If the number of parts per million of each radicle found by analysis be multiplied by its reaction coefficient, a number will be obtained which may be called the "reacting value" of the radicle for that analysis. This will be designated by the letter r prefixed to the symbol of the radicle. Thus, rCa will represent the reacting value of the calcium in any analysis. The symbols of the radicles are used in this paper merely as abbreviations.

The use of the reaction coefficients and reacting values[a] is of great assistance in an attempt to evaluate the effect of mineral impurities on the industrial uses of water. For example, the accuracy of the determinations of an analysis may readily be estimated from the reacting values of the radicles, for in the chemical system which they form the sum of the reacting values of positive radicles must be

[a] The expression of water analyses in terms of reacting values as well as in parts per million has not come into general use, though it has been used and recommended by prominent German chemists for many years.

equal to the sum of the reacting values of the negative radicles. The percentage error due to inaccurate analysis, undetermined radicles, etc., may be found from the formula:

$$(3)\quad e = 100\,\frac{rp - rn}{rp + rn}$$

in which e = percentage error, rp = sum of reacting values of positive radicles, and rn = sum of reacting values of negative radicles. In this calculation iron and aluminum should be omitted, the assumption being that these substances are present as colloidal oxides. Usually, with fairly careful work, e will not exceed 5 in numerical value for waters containing 100 or more parts per million of dissolved solids, and may generally be expected to be 2 or less. A value of e in excess of 5 will indicate: (1) A blunder in analysis or calculation; (2) if negative, the presence of iron, aluminum, or some undetermined positive radicle; or (3) if positive, the presence of silicate or some undetermined negative radicle. Individual judgment must decide which of these causes of error is the most probable and reject the analysis or correct the form of statement in accordance with the magnitude and character of the error and the relative abundance of the radicles likely to be involved. The correction of an analysis in this manner is generally an unreliable makeshift if the error is large, but can occasionally be made with a high degree of probability.

The determinations usually made in examining water for its mineral impurities are summarized below:

	Symbol.
1. (*a*) Suspended matter	Sm
(*b*) Turbidity	Tu
2. Collodial matter	Cm
(*a*) Silica	SiO_2
(*b*) Iron oxide	Fe_2O_3
(*c*) Alumina	Al_2O_3
3. Dissolved gases	Dg
(*a*) Carbon dioxide	CO_2
(*b*) Hydrogen sulphide	H_2S
4. Dissolved radicles	Ds
(*a*) Iron	Fe
(*b*) Aluminum	Al
4. Dissolved radicles—Continued.	
(*c*) Calcium	Ca
(*d*) Magnesium	Mg
(*e*) Sodium	Na
(*f*) Potassium	K
(*g*) Hydrogen	H
(*h*) Carbonate	CO_3
(*i*) Bicarbonate	HCO_3
(*j*) Sulphate	SO_4
(*k*) Chlorine	Cl
(*l*) Nitrate	NO_3

SOAP-CONSUMING POWER.

Whipple [a] has deduced from a series of experiments the cost of consumption of the common household soaps by waters of various degrees of hardness. Iron, aluminum, calcium, magnesium, and

[a] Whipple, G. C., The value of pure water, John Wiley & Sons, New York, 1907; pp. 24–28.

hydrogen radicles in solution are the soap-consuming constituents of water. Therefore, accepting Whipple's values, the cost in cents per 1,000 gallons for soap necessary to produce a lather in water is as follows:

(4) Soap cost

$$= 11 + 50.05\ (rFe + rAl + rCa + rMg + rH)$$
$$= 11 + 1.79\ Fe + 5.54\ Al + 2.5\ Ca + 4.11\ Mg + 49.6\ H.$$

WATER SOFTENING.

Hard water has such a deleterious effect in most industries that the practice of "softening" the water before use has become prevalent in regions where soft waters are not obtainable. The principal so-called hardening constituents are calcium and magnesium, and by reason of their cheapness lime and soda ash are the chemicals customarily used in the softening process. The lime is introduced as the hydroxide, $Ca(OH)_2$, and the soda ash as Na_2CO_3. By the soda-lime method of softening, the hydrogen is changed to water; calcium, magnesium, iron, and aluminum are removed as precipitates; the bicarbonate radicle and carbon dioxide are changed to carbonate radicle and water; and part or all of the carbonate radicle removed as a precipitate. The calcium added as $Ca(OH)_2$, as well as that already in the water, is precipitated as calcium carbonate ($CaCO_3$). The sodium added as Na_2CO_3 remains in solution, taking the place of bases precipitated or otherwise removed from the chemical system. The reactions that apparently take place are:

$Fe + 2OH = Fe(OH)_2$, which falls as a precipitate.
$Al + 3OH = Al(OH)_3$, which falls as a precipitate.
$Mg + 2OH = Mg(OH)_2$, which falls as a precipitate.
$Ca + CO_3 = CaCO_3$, which falls as a precipitate.
$H + OH = H_2O$.
$HCO_3 + OH = CO_3 + H_2O$.
$CO_2 + 2OH = CO_3 + H_2O$.

From the foregoing reactions, it appears that lime must be added in quantity sufficient to provide hydroxyl (OH) to combine with the iron, aluminum, magnesium, bicarbonate, and hydrogen radicles and carbon dioxide. In addition, if the carbonate radicle in the water plus that formed by change of bicarbonate radicle and carbon dioxide is not sufficient to precipitate the calcium present in the water, and added as lime, an additional quantity must be provided by the addition of soda ash in order that all the calcium may be precipitated. This latter consideration determines the amount of soda ash to be added. In terms of pounds of 90 per cent lime (CaO) and 95 per

cent soda ash (Na_2CO_3) per 1,000 gallons of water, these statements may be expressed in the following formulas:

(5) Lime required

$= 0.26\ (rFe + rAl + rMg + rH + rHCO_3 + .0454\ CO_2)$

$= .00931\ Fe + .0288\ Al + .0214\ Mg + .258\ H + .00426\ HCO_3 + .0118\ CO_2.$

(6) Soda ash required [a]

$= 0.465\ (rFe + rAl + rCa + rMg + rH - rCO_3 - rHCO_3)$

$= .0167\ Fe + .0515\ Al + .0232\ Ca + .0382\ Mg + .462\ H - .0155\ CO_3 - .00763\ HCO_3.$

Assuming the average cost of lime to be 0.3 cents and of soda ash to be 1.2 cents per pound, the cost in cents per 1,000 gallons of chemicals for softening a water can readily be determined from formulas (5) and (6), as follows:

(7) Cost of chemicals for softening

$= .636\ (rFe + rAl + rMg + rH) + .558\ (rCa - rCO_3) + .00354\ CO_2 - .48\ rHCO_3$

$= .0228\ Fe + .0704\ Al + .0522\ Mg + .631\ H + .0279\ Ca + .00354\ CO_2 - .0186\ CO_3 - .00787\ HCO_3.$

A negative value for formula (6) shows that no soda ash is required. In such case, instead of using formula (7), take .3 the value of formula (5) for cost of chemicals. Formulas (4), (5), (6), and (7) may usually be simplified for practical use by the omission of iron, aluminum, and hydrogen, for they are not often present in sufficient quantity to affect the results. Total incrustants in parts per million (as determined by the standard method of the American Public Health Association) multiplied by .0093 will be practically equal to the value of formula (6).

Similar formulas can readily be deduced for use in connection with water softening by other chemicals, but their practical application would be small. In connection with the water-softening problems, it should be remembered that the reactions quoted above and the resulting precipitation will vary in completeness with conditions of temperature, mixing, sedimentation, etc. Furthermore, the precipitates formed are not wholly insoluble. In a water softened under ideal conditions there may remain in solution 5.2 parts per million of calcium and 3.4 parts per million of magnesium, together with equivalent amounts of negative radicles. These figures may be

[a] The use of soda ash in water softening results in an increase of the highly soluble constituents, for the sodium thus added remains in solution. In some industrial uses of water a great increase in content of sodium is accompanied by very undesirable results; and if the water contains a large amount of the sulphate radicle, barium carbonate ($BaCO_3$) may be substituted for all or a part of the soda ash to advantage. In such waters the minimum amount of soda ash to be used is, in pounds per 1,000 gallons, $.0131\ Cl + .0075\ NO_3 - .0202\ Na - .0119\ K$. A negative value for this expression shows that the barium compound may be used for all of the soda ash required by formula (6), and if the expression be positive its value should be subtracted from the value of formula (6) to find the amount of soda ash for which barium carbonate may be used. In the substitution, 1.77 pounds of barium carbonate must be used in place of each pound of soda ash and the cost will be increased by 2.7 cents for each pound of soda ash replaced.

increased by the presence of other substances. On the other hand, a very large percentage of colloidal and suspended matter will be carried down with the precipitates, thus increasing the value of the softening process.

BOILER WATERS.

The chief industrial use of water is steam making. The cost of softening water is a fairly reliable index to its value for this and many other industrial purposes. The cost for softening is the sum of two figures—cost for lime and cost for soda ash, the former being about one-fourth the latter. In a general way, the amount of lime required varies with the amount of least objectionable impurities, while the amount of soda ash required varies with the quantity of impurities most deleterious in character. If, therefore, the ill effects of the latter class may be assumed as four times those of the former, the relative cost of chemicals for softening waters will represent their relative objectionableness with a fair degree of accuracy.

The customary method of interpreting the value of a water for boiler use is based on its tendency to cause foaming, corrosion, and incrustation. Such interpretation is usually made from the hypothetical combination of the radicles as salts, judgment of the tendencies of these salts being made in accordance with our knowledge or theories of boiler physics. Unfortunately our knowledge is rather restricted though our theories are numerous. It follows that the interpretation can not always be expressed in very definite terms and if so expressed is liable to error.

FOAMING AND PRIMING.

Foaming and priming are probably the least understood of boiler phenomena. Priming may be defined as an ebullition so violent that water in the form of spray is carried from the boiler before its separation from the steam can take place. It is controlled by the relations of heating surface, evaporation surface, circulation, and working load, all of which are factors of the violence and rapidity of ebullition, and by such features as dash plates, water space, and steam space, all of which affect the possibility of violently boiling water reaching the steam exit. Priming, as thus defined, is a matter of boiler design and operation.

Foaming is the formation of bubbles upon and above the surface of the water. The less easily these bubbles break the higher will the foam rise. It may become so excessive that the bubbles, or films of water inclosing steam, pass out with the steam.

Naturally priming, or a tendency to prime, is an important factor in excessive foaming. Aside from this, the difficulty with which the

steam pushes through the surface film of water and separates from it is a controlling agency. With little mineralized water foaming is very slight and never sufficient to cause the loss of water with steam in a well designed boiler. Nearly all impurities dissolved or suspended in water increase the foaming tendency, though no two substances may do so to the same degree. As steam is used from the boiler the impurities are concentrated and finally a stage is reached which will cause excessive foaming. If, therefore, the quantity of impurities and the effect of each were known, the calculation of the foaming tendency of a water would be a simple matter. Unfortunately, our knowledge of this department of boiler physics is very slight. It is practically impossible to determine the quantity of suspended matter in a boiler at any time. Suspended matter originally present in the water is largely precipitated, while additional suspended matter is derived from loosened scale and from the precipitation of impurities in solution in the feed water. Organic matter holds a similar indefinite place in connection with foaming calculations because a large but unknown proportion is precipitated. It is, however, usually present in relatively small amount in boiler waters. Although both these classes of substances are undoubtedly important, the effect of precipitated magnesium being especially noteworthy, their rôle in inducing foaming can not, therefore, be calculated from an analysis of boiler feed water. For this reason and because all other dissolved substances are relatively insignificant in amount in a highly concentrated boiler water it is generally customary to attribute foaming to sodium and potassium salts. These substances are highly soluble and their relative importance in different waters is easily determined from analyses. The expression $2.7Na+2K$ will represent these salts generally within 5 per cent and always within 15 per cent. It will correspond very closely to the "nonincrusting solids" usually estimated from hypothetical combinations and is sufficiently accurate for practical use. Since these compounds are at best a rough approximation of the foaming tendency of a water, nothing would be gained by the use of a more cumbersome expression from which they could be more accurately estimated. The following formula may, therefore, be adopted:

(8) Foaming coefficient $f=62rNa+78rK=2.7Na+2K$.

It is to be hoped that investigation may lead to a better understanding of this phenomenon and hence to a more reliable index to the foaming tendency of waters.

The steam engineer is interested more in the number of hours his boiler may be run under ordinary load without danger of foaming

than in the coefficient given above. This is really a combined index of priming and foaming and may be calculated from the formula:

(8*a*) Run in hours: $Rh = \frac{a}{b}\left(\frac{c}{f} - 1\right)$,

in which a = water capacity of boiler, b = hourly quantity of feed water used, f = foaming coefficient, and c is a constant which represents in parts per million the concentration of salts that will cause excessive foaming in the type of boiler under consideration.

The usual remedy for foaming is blowing off a portion of the highly impure water and replacing it with fresh feed water. If a in the foregoing formula be made to represent the amount of water blown off at any time, the expression will indicate the length of time that may with safety elapse before blowing off again.

The following approximate values have been determined for the constant c for various types of boilers and are here adapted from Christie's "Boiler waters."

Locomotive boiler	2,500 to 3,500
Stirling boiler	4,000 to 5,000
Modern water-tube boiler (such as the Babcock & Wilcox or Heine)	5,000 to 7,000
Horizontal return tubular boiler	8,000 to 10,000
Old-style two-flue boiler	17,000

From these figures it appears that the locomotive boiler is the type most likely to give trouble on account of foaming and offers, therefore, a satisfactory basis for an arbitrary classification of waters according to their foaming tendency. A nonfoaming water may be defined as one that can be used in a locomotive boiler throughout one week's work without foaming; a semifoaming water as one that can not be used so long as a week, but one that will require one complete water change to avoid foaming in a locomotive boiler not oftener than every two days; and a foaming water as one that can not be used so long as two days in a locomotive boiler without blowing off or changing water to prevent foaming. Accepting these conditions, the following approximate classification of waters will result:

(1) Nonfoaming; f not greater than 60.
(2) Semifoaming; f greater than 60, but not greater than 200.
(3) Foaming; f greater than 200.

CORROSION.

Corrosion of a metal will occur in the presence of water if the metal is capable of replacing any positive radicle in the chemical system which the dissolved matter in the water constitutes. The radicle thus replaced may pass from solution as a precipitate or a gas. In boiler corrosion the metal to be considered is the iron of the boiler. The radicle which it may replace in the chemical system of dissolved solids is hydrogen, which, when so replaced leaves the chemical system

as hydrogen gas. It follows that the amount of hydrogen radicle in the chemical system under boiler conditions is the controlling factor of corrosion. The calculation of this factor can be made with a fair degree of accuracy. Under boiler conditions the dissolved gases are driven out with the steam. Therefore, although some of these substances are prominent corrosive agents when confined they are omitted from consideration here.

Hydrogen radicle as determined by analysis is the first item. It may be the cause of corrosion in the cold or under boiler conditions. To this may be added, as a result of the high temperature in a boiler, three molecules of hydrogen for each molecule of aluminum, two of hydrogen for one of iron, and two of hydrogen for one of magnesium. The reactions involved may be represented by the following equations:

$$2Al + 3H_2O = Al_2O_3 + 6H$$
$$Fe + H_2O = FeO + 2H$$
$$Mg + H_2O = MgO + 2H$$

These reactions probably do not occur in just this way, but they express well-known results. There are other reactions that may cause an increase in the amount of hydrogen radicle. While they will not be considered in the calculations which follow, the three given below are of interest as expressing possibilities:

$$2Fe + 3H_2O = Fe_2O_3 + 6H$$
$$3Fe + 4H_2O = Fe_3O_4 + 8H$$
$$SiO_2 + H_2O = SiO_3 + 2H$$

In all of these equations, except the last, the hydrogen is represented as being brought into the chemical system to replace a radicle precipitated as an oxide. In the last equation, hydrogen and silicate radicles are both brought into the system. In all cases, of course, the equilibrium between positive and negative radicles in the system must be maintained.

Opposed to these reactions increasing the amount of hydrogen are others tending to decrease it. Thus under boiler conditions each molecule of carbonate radicle may combine with two molecules of hydrogen and each molecule of bicarbonate radicle with one molecule of hydrogen to form water and the gas carbon dioxide. This is illustrated by the following equations:

$$H + HCO_3 = H_2O + CO_2$$
$$2H + CO_3 = H_2O + CO_2$$

Thus positive and negative radicles leave the chemical system together.

The carbon dioxide so formed will pass off with the steam.

The two sets of phenomena may be combined to represent the residual hydrogen likely to be replaced in the chemical system by iron from the boiler, as follows:

(9) Coefficient of corrosion:

$$c = 1.008\ (rH + rAl + rFe + rMg - rCO_3 - rHCO_3)$$
$$= H + .1116\ Al + .0361\ Fe + .0828\ Mg - .0336\ CO_3 - .0165\ HCO_3$$

One of the first occurrences in a boiler is the precipitation of at least a part of the carbonate and bicarbonate radicles as calcium carbonate. Such precipitate can be acted upon, the calcium being returned to the chemical system to replace the hydrogen which forms water and carbon dioxide with the carbonate radicle. The extent of such action is not well defined. With a maximum precipitation of calcium carbonate and a minimum action upon the same, the effect of the carbonate and bicarbonate radicles in the above formula may be reduced by 1.008 rCa or .0503 Ca. The foregoing considerations afford an excellent basis for the classification of waters according to their corrosive tendencies. Three classes may be distinguished as follows:

(1) Corrosive. If c be positive, the water will certainly corrode the boiler.

(2) Noncorrosive. If $c + .0503$ Ca be negative, no corrosion will occur on account of the mineral constituents in the water.

(3) Semicorrosive. If c be negative, but $c + .0503$ Ca be positive, corrosion may or may not occur, the probability of corrosive action varying directly with the value of the expression $c + .0503$ Ca.

SCALE FORMATION.

The formation of scale and sludge in boilers is the most common effect of the use of impure feed water. This phenomenon is the result of heating the water to a high temperature and concentrating it. The heat reduces the solubility of many of the dissolved substances to such an extent that they leave the chemical system. Concentration may gradually increase the amount of dissolved matter to saturation, after which additional concentration will cause it to pass out of solution. Suspended matter and colloidal matter are also largely deposited within the boiler.

The purest of natural waters, if used in a boiler for a great length of time without cleaning, would produce scale or sludge. As boilers are usually operated, temperatures and concentrations are permitted which result in the precipitation of practically all suspended and colloidal matter—all iron, aluminum, magnesium, and all calcium to the full extent of its ability to combine with carbonate, bicarbonate, and sulphate radicles. The iron, aluminum, and magnesium appear in the scale as oxides (magnesium carbonate may be present, but is not likely to be found in quantity in scale from high-pressure boilers),

while the calcium may be present as calcium carbonate or calcium sulphate (a hydrated calcium sulphate frequently occurs, but in the modern high-pressure boiler its quantity is sufficiently small to be neglected). Whether these results are caused by a series of reactions or by a single chemical change is of little moment in connection with boiler calculations. The following reactions, therefore, are presented not as formulas for the changes which actually take place, but as equations which express the known results of changes that occur within the boiler:

$$2Al + 3H_2O = Al_2O_3 + 6H$$
$$Fe + H_2O = FeO + 2H$$
$$Mg + H_2O = MgO + 2H$$
$$Ca + CO_3 = CaCO_3$$
$$Ca + 2HCO_3 = CaCO_3 + H_2O + CO_2$$
$$Ca + SO_4 = CaSO_4$$
$$H + HCO_3 = H_2O + CO_2$$
$$2H + CO_3 = H_2O + CO_2$$

The hydrogen in the last two equations may include not only the hydrogen radicle found by analysis, but also that developed by the first three equations. In other words, it is c, the coefficient of corrosion. An estimate of the amount of scale formed is necessarily rather uncertain. The first three reactions may, without great error, be assumed to be practically complete. The division of carbonate and bicarbonate radicles between calcium and hydrogen, and the division of the calcium between carbonate and sulphate radicles, are not definitely known and probably vary with different conditions of boiler operation. On this account it would seem desirable to estimate maximum and minimum values for scale formed by calcium compounds. Formulas were prepared with this in view, but the difference between maximum and minimum values was found to be small in nearly every instance. The use of the necessarily cumbersome formulas was therefore discarded in favor of one which represents a probable average scale-forming value. Calculations based upon this formula are relatively simple, and it is believed that they are of as great practical value as the maximum and minimum formulas. In order to conform to common usage the formula is in terms of pounds of scale per 1,000 gallons of water.

(10) Scale (Sc)

$$= .00833\ Sm + .00833\ Cm + .3\ rFe + .142\ rAl + .168\ rMg + .492\ rCa$$
$$= .00833\ Sm + .00833\ Cm + .0107\ Fe + .0157\ Al + .0138\ Mg + .0246\ Ca$$

In this formula the value of rCa used should not be in excess of $rCO_3 + rHCO_3 + rSO_4$. (Ca should not exceed $.668\ CO_3 + .328\ HCO_3 + .417\ SO_4$).

Formula (10) shows the amount of scale and sludge likely to be deposited in a boiler operated under the usual conditions of modern practice

and its value will never differ widely from the "total incrusting matter" frequently reported from an estimation of hypothetical combinations of radicles. It is of equal importance to know whether the matter deposited will form a hard scale. The following formula shows in pounds per 1,000 gallons the probable amount of hard-scale forming material in the scale:

(11) Hard scale (Hs)

$= .00833\ SiO_2 + .168\ rMg + .567\ (rCl + rSO_4 - rNa - rK)$

$= .00833\ SiO_2 + .0138\ Mg + (.016\ Cl + .0118\ SO_4 - .0246\ Na - .0145\ K)$

The value used for the parenthesis of this formula must not exceed rSO_4 or rCa ($.0118\ SO_4$ or .0283 Ca in the second form) nor should it be less than zero.

Dividing the value of formula (11) by the value of formula (10), a factor will be obtained which may be called the coefficient of scale hardness. This factor shows the proportion of the total scale that is likely to form a cement-like substance upon the boiler tubes and is therefore an index to the probable hardness of the scale that will be deposited. Thus:

(12) Coefficient of scale hardness, $h = \frac{Hs}{Sc}$

From formulas 10, 11, and 12, waters may be classed as follows:

(1) Soft scale: h not more than .25.

(2) Medium scale: h more than .25 but not more than .5.

(3) Hard scale: h more than .5.

In addition, the following classification may be used as a prefix to the preceding:

(1) Very little: Sc not more than 1.

(2) Little: Sc more than 1, but not more than 2.

(3) Much: Sc more than 2, but not more than 4.

(4) Very much: Sc more than 4.

IRRIGATING WATERS.

An excess of alkali in the soil is detrimental to the growth of crops, and waters used in irrigation may seriously impair the fertility of land by augmenting its alkali content. Land would probably be injured by the best of natural waters if irrigated with them for a long period of time without natural or artificial drainage, for all irrigating waters contain alkali, and evaporation in and from the soil would result in a gradual accumulation of toxic salts. In order that waters may readily be compared with respect to their suitability for irrigation, a simple index of their irrigating value should be available. The calculation of such an index, designated the "alkali coefficient," is developed in the following paragraphs. The alkali coefficient is a purely arbitrary quantity intended solely to

facilitate the comparison of waters to be used for irrigation. It may be defined as the depth in inches of water which, on evaporation, would yield sufficient alkali to render a 4-foot depth of soil injurious to the most sensitive crops. Thus, if the alkali coefficient of a water is found to be 17, 17 inches in depth of that water contains sufficient alkali to render injurious to sensitive crops the soil on which it is applied. Whether injury would actually result from the application of such a water to any particular piece of land, however, depends on methods of irrigating, the crops grown, the character of the soil, and drainage conditions, and it should be clearly understood that the alkali coefficient in no way takes account of such conditions.

Hilgard [a] quotes results of investigations by R. H. Loughridge showing the greatest amount of various alkali compounds found in soils in which crops were not injured. About forty common cultures were included in the tables, and great diversity is indicated for the relative toxicity of the compounds toward the different cultures. The mean results for several cultures of about the same degree of sensitiveness, however, indicate with marked uniformity the relative toxicity of the alkalies toward common cultures to be about as follows: Sodium as Na_2CO_3, 10;[b] sodium as NaCl, 5; sodium as Na_2SO_4, 1. The investigations indicate further that about 1,500 pounds per acre of sodium with a relative toxicity of 1 (as above) in 4 feet depth of soil is barely sufficient to affect injuriously the more sensitive common crops. The foregoing conclusions, being in accord with the results of other investigations, will be used as a basis for the calculation of the alkali coefficient, which may be made from a water analysis by means of the following formulas:

(13*a*) When rNa − rCl or Na − .65 Cl is zero or negative,

$$\text{Alkali coefficient, } k = \frac{288}{5rCl} = \frac{2040}{Cl}$$

(13*b*) When rNa − rCl or Na − .65 Cl is positive but not greater than rSO_4 or .48 SO_4,

$$\text{Alkali coefficient, } k = \frac{288}{rNa + 4rCl} = \frac{6620}{Na + 2.6Cl}$$

(13*c*) When rNa − rCl − rSO_4 or Na − .65 Cl − .48 SO_4 is positive,

$$\text{Alkali coefficient, } k = \frac{288}{10rNa - 5rCl - 9rSO_4} = \frac{662}{Na - .32\ Cl - .43\ SO_4}.$$

In the foregoing formulas, the sodium and potassium value reported in many analyses may be used for Na; in the absence of a

[a] Hilgard, E. W., Soils, p. 467, 1906.

[b] The tables indicate a relative toxicity of about 6, but on account of the puddling effect of sodium carbonate on soils and the fact that the investigations did not distinguish between bicarbonate and carbonate of sodium, the value 10 is believed to be more satisfactory.

sodium or a sodium and potassium determination, Na may be estimated from the equations

$$Na = .41\ HCO_3 - .83\ CO_3 - .71\ Cl - .52\ SO_4 - (1.25\ Ca + 2.06\ Mg)$$
$$rNa = 1.10\ [rHCO_3 + rCO_3 + rCl + rSO_4 - (rCa + rMg)]$$

which for safety give a value about 10 per cent greater than the theoretical; and in the absence of calcium and magnesium determinations, the foregoing equations may be used if the parenthetical expression be replaced by one-half the total hardness (as $CaCO_3$) or its equivalent reacting value.

Formula (13*a*) is applicable to waters that contain more chlorine radicle than is sufficient to combine with the sodium present, and involves the assumption that the other basic radicles required to hold the chlorine radicle in solution are as injurious as if replaced by their equivalent reacting value of sodium. The other formulas neglect possible injurious effects of basic radicles other than sodium. These assumptions, as applied to normal waters, are sufficiently accurate for practical purposes, though their application to soils might lead to serious errors.

Waters to which formulas (13*a*) and (13*b*) are applicable can not be improved by chemical treatment, but are likely to produce only "white alkali" in the soil. Waters to which formula (13*c*) is applicable are likely to produce "black alkali" in the soil and can be improved to the alkali coefficient calculated from formula (13*b*) by the use of gypsum or "land plaster."

In general, injurious results from the use of a water for irrigation depend largely on drainage conditions and soil texture. Waters with low alkali coefficients may be used successfully on a loose soil with free drainage. The following approximate classification, which is based on ordinary irrigation practice in the United States, indicates in a very general way the customary limitations in the use of waters having various alkali coefficients:

Classification of irrigation waters.

Alkali coefficient.	Class.	Remarks.
More than 18	Good	Have been used successfully for many years without special care to prevent alkali accumulation.
18 to 6	Fair	Special care to prevent gradual alkali accumulation has generally been found necessary except on loose soils with free drainage.
5.9 to 1.2	Poor	Care in selection of soils has been found to be imperative and artificial drainage has frequently been found necessary.
Less than 1.2	Bad	Practically valueless for irrigation.

APPLICATIONS.

The foregoing formulas will now be applied to a few analyses, which, for convenience, have been arranged in the form of statement herein suggested.

Below are given the results of calculation of the various formulas presented and classification of the waters in accordance therewith.

Analyses of waters and results of formulas.

[Parts per million.]

13. Alkali coefficient, k	290	440	22	280	2.6

Analyses B and D seem to be somewhat in error. The errors indicated could be accounted for by the presence of iron and aluminum radicle in the one case and by silicate radicle in the other. The differences are not great enough, however, to warrant a change in the form of statement. Hence iron, aluminum, and silicon are presumed to be present as oxides in the colloidal state.

The following boiler classification of the waters (including a verbal and a numerical classification) will result from the foregoing figures:

(A) (15) Nonfoaming, (−0.44+0.11) semicorrosive, (0.59) very little, (0.20) soft scale.

(B) (21) Nonfoaming, (+0.42+1.23) corrosive, (1.51) little, (0.37) medium scale.

(C) (130) Semifoaming, (−1.58+1.63) semicorrosive, (1.84) little, (0.46) medium scale.

(D) (30) Nonfoaming, (−0.49−0.08) noncorrosive, (0.46) very little, (0.25) soft scale.

(E) (1057) Foaming, (−9.69−8.28) noncorrosive, (0.94) very little, (0.23) soft scale.

The effect of suspended matter upon the scale classification of B is of interest. Neglecting the suspended matter, the class would be "very little hard scale."

For use in irrigation, E would be classed as poor and the others as good.

For detailed comparison or classification of waters, the formulas presented will be found of great value. It is believed that a better general understanding of waters and much practical advantage would result if the analyst were to devote to the foregoing calculations and the resulting classification a portion of the time usually spent in figuring hypothetical combinations.

For those who desire to use the formulas the following notes are of special interest:

(*a*) The reacting values are necessary only in estimating the error of analyses. Other formulas are presented in dual form so that reacting values may be used or not, as desired. Generally their use will shorten the work of calculation.

(*b*) The formulas are well adapted to the use of a slide rule or similar calculating machine. They are for use primarily in connection with analyses expressed in parts per million or milligrams per liter, but can be used for analyses expressed otherwise if such analyses are reduced to parts per million by multiplying by the proper factors, as follows:

Parts per hundred thousand—10.
Grains per U. S. gallon—17.1.
Grains per imperial gallon—14.3.
Pounds per thousand U. S. gallons—120.
Pounds per thousand imperial gallons—100.
Per cent of dissolved solids—total dissolved solids in parts per million or milligrams per liter.

(*c*) The numerical coefficients used in the formulas are the result of the simple mathematical calculations of chemistry. Thus the coefficient 0.26 of formula (5) is derived as follows: It is desired to find the quantity of lime (CaO) that will react with certain substances. The reacting value of this lime must, of course, equal the sum of the reacting values of the substances with which it is to react. The parenthesis of the formula represents this reacting value. The reacting coefficient of CaO being $\frac{1}{28.05}$, our reacting value for lime must be multiplied by 28.05 to give parts per million of CaO. This must in turn be divided by 120 to give pounds per 1,000 gallons. A final division by .90 reduced the expression to terms of lime of 90 per cent purity. Thus $28.05 \times \frac{1}{120} \times \frac{1}{.90} = 0.26$. Other numerical coefficients of the formulas are derived in a similar manner.
